HI,

The 1 meter loop for MW broadcast reception works best when tuned ....
making a remote attic location a problem (remote tuning is possible of
course). The loop works best when inductively coupled to radios like the
S350 which uses a tuned ferrite loop front end. If you imagine the tuned

front end of the S350 to be the pickup loop you can see that the best 'placement' is not a fixed relationship .... the amount of coupling that works best varies.

I find that a tuned loop with a coupling/pickup loop works best with radios that are shielded and do not have a built in ferrite tuned front end/ antenna. they also have a balanced input. As a consequence coax feed line is not the best solution unless used in conjunction with some kind of balun arrangement. It is just as easy to use parallel feed line such as a twisted pair, zip cord, or speaker cable. There is really no need for coax if you couple the balanced pickup loop to balanced cable to a balanced radio input.

I have an excellent AM radio in my HI-FI setup which has a balanced input. I moved my box loop around the living room to the best (quietest) location and run a feed line made of parallel speaker cable to the radio (25 ft). I put the radio on the frequency of choice (digital tuning) and just touch up the loop tuning. Great listening !!

Now if I were to put the loop in the attic I would have to devise some means of remotely adjusting the loop tuning. there are only about 3 DX stations I regularly listen to ... so I suppose the easiest method would be to use 3 capacitors .... each tuned to the station of choice and switched in with relays.

PS my pickup loop is adjustable .... it is about 8" in diameter and consists of 4 turns of hook-up wire on a plastic loop. It's position can be changed by slightly rotating it on its axis which changes in relation to the loop axis (about 2' in diameter). Adjust the loop for the 'just right' spot ... between amount of pickup and maximum loop Q. The 'just right' coupling is only critical with the weakest dx stations.

Jim

6989. Two wellbrook antennas

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-12-29 16:12:29 UTC
From: Marc
Topic: 6989 Message: 6989

Hello,

I suppose this loop is better for am/lw than the "original" ala1530:
http://www.wellbrook.uk.com/antennashop/index.php?route=product/product&path=35&product_id=41

orig 1530
http://www.wellbrook.uk.com/antennashop/index.php?route=product/product&path=35&product_id=28

I see a 40db against 30db for noise rejection.

Anybody any experience??

Marc

Date: 2009-12-29 18:46:14 UTC
From: Tom Garden
Topic: 6982 Message: 6990

The small loop´s diameter is around 1/5 of the tuned loop diameter. Usually it is positioned at the oposite side of place where the tuning capacitor is fixed.

Eduardo,
That was a good post about loop antennas, it helps me because my long-wire antenna fell down in high winds last night, after 7 years.
Do not be sorry for your English! You know it well, and type it well.
Thank you Eduardo in Brasil.

Hello, good night and Merry Christmas to you and all your family. Well in the case of this receptor is not necessary that you do the "loop" procedure, simply bring the receiver antenna, below the wires and fine-tune your radio and antenna. Ready this is the best result, but if you prefer to connect the coaxial cable, make a loop of 50 cm in diameter and place the center of the antenna (the table) and connect a coaxial cable with good quality in your receiver, also is a good option, but rather only the approach to this case, as in the medium wave receiver has a ferrite antenna inside.
The cable for connecting the antenna to the radio, not necessarily a thick cable, you can even use a thinner cable and even a wireless connection to speakers, the result is satisfactory, what you can do is to use cable between the antenna and radio too large, it creates a signal and also changes the characteristics of the antenna, which can vary the frequency pre determined. I have a dish of medium wave and to use only the antenna by induction.
Good luck and I hope I have helped you, sorry for my English.

6992. Well, It's Not Exactly A Loop....

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-12-30 14:10:09 UTC
From: march181959
Topic: 6992 Message: 6992

Ok, so I dug up this old idea when my longwire went down in the last snowstorm. I needed something strong to withstand the New England winter. I picked up a metal Slinky while Xmas shopping. The Slink is hanging from a hook at the corner of the house where the roof meets the wall, and then it stretches vertically to the ground where I attached it to a metal rod buried in the ground. A wire runs from the top of the Slink into a coax which has an inline balun, and then downstream of the balun the coax plugs into the radio. The dB signal has tripled and is at least as good as the longwire, and of course, I can pick up stations that I can't detect without the Slink.

Do you think that a one loop tuned coil wire inside the Slink would act like a real coil? Anybody know of any 12 ft long ferrite rods..he heee?

Frank in Boston

Some time ago, John Popelish came up with the idea of using a string of toroids instead of a solid rod. You might want to join the Yahoo! group that he runs:

http://groups.yahoo.com/group/ferriterodantennaexperimenters/

He built them by using a piece of insulated material, such as a plastic rod or wood dowel, and then simply stacking the toroids. There were a number of variations, such as epoxying the toroids together or using a piece of heat-shrink tubing to hold them together. This is much cheaper and certainly more readily obtainable than those large rods.

Using toroids is every bit as good as a solid rod, perhaps better at low frequencies as the gap between the toroids decreases the hysteresis and eddy current losses. In magnetic materials, the bulk of the flux is in a thin layer at the surface, known as "magnetic skin effect", which is the same concept as the skin effect in electrical conductors.

You can buy large ferrite and powdered iron toroids by the truckload from Amidon.

Mike,
During WW2 when electric fires were unobtainable we were given a 1930's model.
This had a copper dish reflector appx 15 in dia and the element coil was wound on a ceramic former about the size of a 150 watt light bulb that plugged in.
Anyone know what type of wire elements are made of ????

Nichrome (sometimes called nichrome V) is a common alloy for
such heating elements. Kanthal is another trade name for
one of these high melting point alloys made of nickel,
chrome, and sometimes iron and aluminum.

I have experimented with many large rods made up of stacks
of large ferrite shield beads. Digikey sells these in
several grades that are optimal in different frequency ranges.
for example:
http://search.digikey.com/scripts/DkSearch/dksus.dll?Detail&name=240-2138-ND
http://search.digikey.com/scripts/DkSearch/dksus.dll?Detail&name=240-2081-ND
http://search.digikey.com/scripts/DkSearch/dksus.dll?Detail&name=240-2154-ND
These have peak Q around 500kHz, 1MHz and 2MHz, respectively.
I found the Q was higher with thin spacers (a mil to a few
mils) between the beads in the stack.

Note that the material these are made of is not quite as
good as the stuff intended for antennas, because these are
meant to be used to absorb energy traveling through cables
passed through them. Their BH loops are fatter than antenna
material. But they work pretty well considering the price
and availability.

I also purchased some impeder rods (intended to be used in
pipe seam welding, made of high permeability (low frequency)
power ferrite material. They are about 3/4 inch in diameter
but with a petal pattern in cross section and about 8 inches
long. I sold most of them to members of several Yahoo!
antenna groups but still have a few left. I haven't had the
time to experiment with mine, and have not heard much from
others who bought them. I can part with a pair of what I
have left. If you might want them, email me for details.

Lots of those radiant heaters had the heating element made
on a conical ceramic form with a lamp base so it could be
replaced by just screwing in a new one.

I've seen old heaters use this type element:

http://www.w4dex.com/temp/heating_coil.jpg

I have two sizes, the smaller I think is 600w and the one in the picture is 1000 watt. Some years ago I had a load bank of these elements for testing a 400 cps inverter system.

Hi,
An excellent idea in an emergency. If you Google Slinky Antennas, ther are lots of ideas. Most Radio Hamms decry the use of slinky's, probably because it does not cost loads of money. lol. i always say if it works, use it, and don't bother whether its trendy and expensive. Please keep us informed as you experiment.
Best 73s.

Hi. If using a slinky PAINT IN as it will rust, just drop the whole slinky into some paint and let it hang dry, or use varnish. I understand there are coated types for sale AT A PRICE but I think there all in the US, done here in the UK as yet, 3 in a line will get you on 160 metres - I read in Practical Wireless, use a cord to hold it up, the good thing is the birds willnot crash into it due to the coil size, there are BTW 3 size type, all for now. mbe Mike UK.

hi i use slinkys on a indoor mw flag antenna and it works great check out the rest of my videos on how it performs .. i have had peru west coast usa etc on mw and a couple of so call uk firsts on mw and also several alaskans on mw here in scotland and the antenna is indoors so they do work.

the only difference now is the feed and the resistor are fed on the middle of the vertical legs ... happy new year all cheers david ... ayrshire scotland

John,
Thanks for the rundown on element wire, it is
possibly too brittle for antennas hi!
The resistance must be quite high to do that job.
Regards,
72, Brian, G0NSL-QRP.

From: david feldman
Topic: 6993 Message: 7013

Hello, and thanks for the several very helpful replies.

Thanks for the pointer to stormwise; I was not aware of them.

I want to build an electronically tunable, receive-only mobile HF antenna mainly for 160/80/40 meter bands, tuned with a varactor diode as part of a feedpoint matching network.

After learning of a very interesting paper written by Chris Trask (thanks, Chris!!!) a couple of months ago, I successfully reproduced his varactor matcher for a small receiving loop (now lives in the back yard and is a great 80-40-30M antenna), so I'm inspired now (with parts on order, and anxiously awaiting the long-backordered miniVNA) to make something along these lines (ferrite transformers and a varactor biased with a bias-tee) with a ferrite loopstick antenna that would be attached (maybe horizontally) to the roof rack of my car (yes, the car roof is steel, so this may be a distraction, but I'm looking forward to the learning as much as anything...) I appreciate the pointer to the idea of making a loopstick-style ferrite element from toroid cores or presumably some kind of giant ferrite beads (now I wish I had bought some when I saw them for sale a while back!)... I have just submitted a join-request to join John's ferriterodantennaexperimenters yahoo group, so this should be very helpful too.

Thanks, everyone - all of the messages were much appreciated and perhaps my new commute can be made interesting with such an antenna (using a Kenwood TH-F6AT as the receiver; it's a good receiver for HF provided the antenna is selective!)

7014. slinky versus straight wire question

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-01-01 01:14:01 UTC
From: Dean Wayman
Topic: 7014 Message: 7014

I have been trying to figure out a way to get some wire up in my crawl-space on the second level of my house .

I am only interested in MW at the moment and the lower part of SW , I want the antenna that i make to be very quiet ,I found the plans for the T2FD antennas last night and think it would be very good ariel for me but in order to make one for 500-1700 Khz it looks like it should be on the order of 300 feet long? i don't have that much room. Iv'e read these are very broadband so maybe it would'nt need to be that long .

Then your setup with the slinkys got me thinking? does the extra wire in a slinky (being in a coil)act like a longer antenna ?

In other words ,because of the coils in the slinky is there more wire up than just the physical length of the slinky?

Another question i had ,is there a null with the flag antenna?

Anyway i would be very interested in how you made your antenna if you would like to post a diagram and specs?

Thanks

Dean_0

>broadband so maybe it would'nt need to be that long .

loop type balanced antennas tend to be quieter than dipole type balanced antennas .... and much quieter than antennas end fed against ground. Since you are interested in MW and lower HF reception you will by definition be using a "small" loop with very low signal strength to the receiver (assuming an untuned loop) with broadband coupling. Putting such an antenna some distance from the receiver will require coupling to a feed line .... in such a way as to maintain loop and feed line balance .... so as to reduce or eliminate common mode currents (a good source of noise). A receiver with good sensitivity is required ... or an axillary broadband amplifier could be used (best located at the antenna feed point).

>Then your setup with the slinkys got me thinking? does the extra wire in a
>slinky (being in a coil)act like a longer antenna ?
>
>In other words ,because of the coils in the slinky is there more wire up
>than just the physical length of the slinky?

The only thing a length of slinky adds to an antenna X feet long over a straight wire X feet long is additional inductance. The added inductance could be used strategically in certain antenna configurations to achieve resonance .... or to achieve certain phase shifting. In either case the resonance or phase shift is frequency dependant .... antithetical to the concept of a broadband function.

>Another question i had ,is there a null with the flag antenna?

The Flag antenna and other similar type antennas are technically broadband loops with the low noise characteristics, desirable in achieving a good S/N ratio .... however they are special loops that by virtue of shape, resistive terminations, and strategic feed points achieve a directional radiation pattern .... usually a cardiod shape. It is possible to cause antenna currents within the loop to be maximum in certain portions and minimum in others .... causing those portions with current to act in a

similar fashion to a yagi antenna. To answer your question ... yes, it is possible to rotate the whole affair such that minimum reception in the pattern can point in different directions.

Jim

I'm hearing from a number of people lately who have made this antenna. It was the result of a more ambitious project to make a remotely tuned transmitting loop antenna that did away with the Faraday matching loop or the Delta matching, which many people did not care for. The result was similar to the varactor-tuned receiving loop, but with a motor-driven variable capacitor in place of the varactors:

http://www.home.earthlink.net/~christrask/Paper012.html

>
> so I'm inspired now (with parts on order, and anxiously awaiting

Ferrite loopsticks are a bit tricky due to the high impedance when parallel tuned as well as the terribly low voltage or current when the number of turns is reduced to accomodate the varactor capacitance. I designed an active ferrite loop with remote varactor tuning that you may be interested in:

http://www.home.earthlink.net/~christrask/Paper006.html

This approach uses a small toroidal inductor in parallel with the loopstick, so a large number of turns can be used on the loopstick to get a higher signal voltage when the smaller inductor is parallel tuned with the varactors. Painfully simple, but very effective.

Chris

7018. Re: slinky versus T2FD

Hi Dean.
I am a great fan of the T2FD, never put one in a loft mind but its an idea I have been thinking of.
I am in no way tech in these things so a lot of suck it and see.

My garden is 40 ft long and the T2FD just about fitted in I inverted "Ved" it as well, the spacing was 3ft, the tuning was 7-30 MHz I understand a spacing of 5 ft may have got me to 5 MHz must try that this summer, as to using a slinky the extra wire may do the trick over a distance of 40 ft and bigger spacing, bringing the freq down to 3/4 megs who knows.

It was as I said a great antenna I got to Diego Garsear in the Indian Ocean on 10 watts beating a pile up on 20 Mt's.

Your need a non terminating 680 ohm resistor hope you can get that OK or make one up from a pile of mixed resistors.

You can buy ready made T2FD but the price is megger bucks.

HERES A GOOD TIP, use overhead telephone line wire that the guys no longer want, its steel/copper I think! very strong.

Hope this helps

Our club has the similar B&W folded loop that we attempted to use on Field Day. It just did not put out. SWR was excellent on all bands tested, but it radiated like a dummy load. The club president drove home a few miles away and could not hear it at all.

In the end, we had only one antenna, mine, a homebrew Buddipole variant, and all contacts made that day were on my antenna.

The T2FD gets very mixed reviews.

From: david feldman
Topic: 6995 Message: 7025

Here's a question -

I looked at stormwise.com as a possible source for large ferrite rod to use in such a project, but they're not cheap, so I'm doing some research. I suspect (but haven't tried to confirm) that stormwise rods are internally a string of large ferrite beads like those put over coax to build a RF choke (or otherwise control EMC on a round cable), packed into a piece of PVC tubing readily found at local hardware store.

I found a source for EMC control beads at mouser (I'm sure there are many other varieties and distributors, but I have an order at mouser going out soon so I'm interested if these might be suitable). The catalog page I'm looking at is at the bottom part of the page below.

http://www.mouser.com/catalog/catalogUSD/640/956.pdf

These particular beads are made by steward (acquired by Laird Technologies). On Laird's website, the "28" prefix corresponds to a bead suited to tens of MHz frequencies (they have a lower- and higher-frequency material).

So my question is this - if indeed stormwise large ferrite rods are indeed a bunch of big beads packaged in PVC tubing (and there are no convenient sources for monolithic ferrite rods in the 1" diameter range), then I'd like to experiment with making my own such ferrite rod so I can try variations.

Any comment or suggestion on taking this approach to build a loopstick's ferrite rod core (or other suggestion to source such beads, etc.?)

Thanks,

Dave

Chris, a question about the circuit. I am accustomed to seeing the "opposite" kind of loop to tuned circuit coupling, I mean, a low inductance small turns winding either in series with the main tuned L or tapped onto it. I wonder, how does the self-inductance and shunt capacitance effect of the large antenna winding affect the L1 tuned circuit. I would expect the shunt capacitance to limit the tuning range of L1. Also, you say the turns on the antenna winding can be adjusted for other tuning ranges. So what criteria do we apply when doing this, for the number of turns = self resonance of the antenna winding? Also, if more turns on the antenna winding => higher voltage developed, what defines the upper limit of turns here?
Also, one post mentioned buiiding this for a mobile loop. That reminded me of an article I saw in Wireless World (UK) that had such an antenna for vehicle MW reception - but it used two loops, at 90 degrees, and a simple phase shift circuit, to offset the signals by (if i recall) something like 30 degrees so that there was never a null signal point. That was to eliminate loss of the signal while driving. Of course the magnetic antenna benefit of disfavoring electric field noise still applied. -Hue Miller

They are suited to absorb energy over a wide range of
frequency, but make good, high Q rods only at the lower end
of that range. Type 28 can be pushed (with thin shims
between beads to work pretty well through the AM band, but
their permeability is falling and their losses are rising
fast above 1 MHz.

I have built many test rods with this brand of bead with
pretty good results. For frequencies below 500kHz, I had
better results with the LFB (low frequency bead) material
cores. I like the ones that fit inside 1/2 or 3/4 inch thin
walled PVC pipe. LFB174095-000 is 17.4mm diameter by
28.58mm long and cost about $2 each (out of stock at the
moment at Digikey, unfortunately). Though they do not
appear on the page you listed, Mouser appears to have some
in stock.

Going all the way up to 1 inch diameter beads showed no
improvement over these smaller ones in my tests (up to 1
foot long rods). Perhaps at two feet length and below

100kHz, there might be an advantage of the larger diameter.

Topic: 7028 Message: 7028

Thanks for the info everyone!

After much studying on the net i finnaly decided on a loop antenna ...sorta?

This is for recieve only

It was my intention to build a T2FD but i noticed it would have to be much bigger than the space i had available. And the reviews don't seem that great .

I also found plans for the Flag and pennant antennas but they also needed more space than i had ,so i decided to run a wire in the space i had and see what would happen, it's just a simple rectangle loop 45 feet long and 4 feet or so high ,center fed ,I may put a resistor and a balun on it later ,but for now i'm going to test for a few day's.

So far it seems quiet , on the upper part of AM .
I did a little SW too and it seems to work ok .

Subject: [loopantennas] RE: Sourcing 1

Here's a question -

I looked at stormwise.com as a possible source for large ferrite rod to use in such a project, but they're not cheap, so I'm doing some research. I suspect (but haven't tried to confirm) that stormwise rods are internally a string of large ferrite beads like those put over coax to build a RF choke (or otherwise control EMC on a round cable), packed into a piece of PVC tubing readily found at local hardware store.

I found a source for EMC control beads at mouser (I'm sure there are many other varieties and distributors, but I have an order at mouser going out soon so I'm interested if these might be suitable). The catalog page I'm looking at is at the bottom part of the page below.

http://www.mouser. com/catalog/ catalogUSD/ 640/956.pdf

These particular beads are made by steward (acquired by Laird Technologies) . On Laird's website, the "28" prefix corresponds to a bead suited to tens of MHz frequencies (they have a lower- and higher-frequency material).

So my question is this - if indeed stormwise large ferrite rods are indeed a bunch of big beads packaged in PVC tubing (and there are no convenient sources for monolithic ferrite rods in the 1" diameter range), then I'd like to experiment with making my own such ferrite rod so I can try variations.

Any comment or suggestion on taking this approach to build a loopstick's ferrite rod core (or other suggestion to source such beads, etc.?)

Thanks,

Dave

Hi Dean. Glad you were happy with all the advice given re T2FD and Slinky - even mine LOL, I too am going to put as a test a FLAG in the loft, my loft is smaller tan yours being 30ft long but 5ft high, hope we can report both our results. UK mike.

7031. 160 /80 mtr loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-01-03 11:02:48 UTC
From: richard
Topic: 7031 Message: 7031

Hi all
re earlier postings, of intending to use the VHF/SHF array as a frame for a 4 turn loop.

Has anyone used 1mm 3 + E cable , its the flat cable with 4 cores with about 1.5 mm spacing between
each wire, PVC coated. ?

Do you need to tune the loop with a capacitor ?
The circumference of this loop is going to be 20 mtrs, I was thinking maybe
for 20 mtr use short all four wires together.
for 40 mtrs use the 4 core as two pairs.
for 80 mtrs connect the 4 cores in series
and for 160 mtrs a gurt big capacitor across the 4 cores in series.
I could use relays at masthead to switch the elements.

I had a look at the links already suggested..
As this loop is rotatable would I see any directivity on the lower bands ?

and direction of maximum radiation , is it end on or side on.

As soon as the weather warms up a bit I'll get outside and play, but until then its ask questions.

Thanks

Hi. Would not flat cable or could you be saying ribbon cable make the turns far too close.
uk Mike.

I'm not sure Mike, its going to have to be a bit of a compromise as the top antenna on the array is
a 67 element for 23 cms (1296 MHz). With the total cable width of about 1 cm., I should be able to
get away with passing the cable over the end of the boom on that antenna. The boom is 15 mm square
section. If I space out the turns it may have an effect on the 23 cms antenna, ie loss of gain or
skew the main lobe.

People with large arrays on VHF upwards dont normally have much interest in the LF bands and vice
versa.

Hi all I've done a bit more trawling and found a very useful loop antenna calculator

http://www.saunalahti.fi/hohtola/ham/magnetic-loop-for-80m/magnetic-loop-for-80m.htm

look at the OH7SV Magnetic Loop Calculator (Excel file).

Putting in the dimensions it looks as if my idea will work, with one hickup, due to the diameter of
the wire the efficiency drops to about 1%

Anyone got a source of low cost variable vacuum caps 100pF, I cant see any under about £60

TIA

Hi Marc

yes the old version works OK
Could you please explain the term edge length please.
I assuming that loop width is the diameter of the loop, is edge length the circumference ?

Thanks

see thread 160m loops about a week ago
Its for transmitting and receive on the Amateur radio bands at 1.8 MHz, 3.5-3.8 MHz & 7.0-7.2 MHz.

Hi all

Now I've got this 12' dia loop nearly constructed, how critical are loop to nearby objects
?
ie could I mount it on the side of the tower with say a 4' standoff between the tower and
the
loop ?.

Or could I mount it on a 2" dia Aluminium pole fixed at the top and bottom with just 1"
separation
between the loop and pole ?
TIA

I have done a lot of experimenting with a 160 meter loop (20 ft
perimeter) and found that nearby objects are quite detrimental
if you want to get a sharp null. Certainly, 4 ft from a tower
is a non starter. BTW, I have found that 12 ft diameter is
too large to get a good null even on 160 meters, let alone
higher bands.

Thanks for the reply Rick, I'm not too worried about the null., but the radiation efficiency is
important . So As you susggest forget the tower and I'll mount it on a pole away from the house.
I've used OH7SV's spreadsheet and the gain/efficiency makes huge improvements when conductor
diameter is increased, Hence the reason that designs for 80 mtr loops use 22mm / 3/4" conductors.

The price or Cu is still high and 22mm tube is about $8 /mtr, hence the reason for constructing out
of LDF4-50 .

However when it comes to a 160mtr loop, using Matti's spreadsheet would suggest that a very large
diameter conductor would yield the best results.
Also at 160 mtrs is the RF still being conducted on the surface of the conductor , or is it starting to behave as at lower frequencies by using the whole conductor ?, At the next band down
that's usable 136KHz its very questionable.
I suspect that for LF transmitting loops it may possible to get high efficiencies and gain from
using long strips of aluminium 500mm wide riveted together to form a large loop.

Enter Results
Inductance (uH) 10.440
Frequency (MHz) 1.8 Capacitance (pF) 748.8
Loop conductor length (m)20 XL = XC (ohms) 118.1
Conductor diameter (mm) 500 Distributed C (pF) 53.8
RF power (W) 30 Tuning capacitance (pF) 695.0
Main loop diameter (m) 6.366
Feeding loop diameter(m)1.273
Radiation resistance (ohms) 0.042
Loss resistance (ohms) 0.004

Parallel resistance (kohms) 151
Efficiency (%) 90.3
Compared to ideal loop (dB) -0.44
Loaded Q 1281
Bandwidth -3dB (kHz) 1.4
Capcitor rms voltage (V) 2130

With this loop the tuning cao would be 618pF to resonate at
1.9 MHz , so roughly 1pF/1kHz

I haven't make the correction for the surface area of the conductor , the circumference of a 500 mm
diameter conductor is about 1.5 mtrs whereas a sheet of 500 mm X 1mm is 1.002 mtrs.
This surely begs the question that if the RF current is still 100% flowing on the surface of the
conductor, the thickness of the conductor if sheet is used can be reduced substantially, maybe to
the point of aluminium cooking foil being used.
The extra wide stuff found in supermarkets at Christmas and in the US around Thanksgiving would
take the circumference back up to 1.5 mtrs.
Making a very low cost antenna after the problem of supporting the foil is solved .

Food for thought ?

You didn't say you wanted to use the loop for transmitting. Why would
you want to do that instead of shunt loading your tower?

I had thought of the same idea using adhesive backed aluminum
tape that is sold for stove pipe joints. The problem is that the
Q is already in the 100's even if you make the loop out of RG6
coax as described in my National Contest Journal article
(pdf at: http://www.n6rk.com/loopantennas/NCJ_loop_antenna_N6RK.pdf).

If I made one out of 4 inch plastic pipe covered with foil, the
Q would easily be over 1000. That gives a bandwidth of only a few
kHz on 160 meters. The voltage across the tuning capacitor at
any significant power would be astronomical.

And that's why loops are only for receiving IMHO.

There are alternatives. If maximum transmitting efficiency is the goal then a 1/4w circumference loop made of wire would work very well if you feed the antenna next to the tuning capacitor where the impedance is much higher and the resistive losses are minimized.

See Ben G0CWT's web site: http://g0cwt.co.uk/magloops/
Review all the above thoroughly.

I built an 80M wire magnetic loop using Ben's feed method and use it with great success on both 80M and 160M. Mind you stealth is what I had in mind and this fit the bill.

Shunt loading the tower~ maybe, but there are a lot of expensive electronics up there, there are
microwave transverters for 13 cms and 6 cms as well as masthead pre-amps for 23 cms, 70 cms & 2mtrs.
The base of the tower is well earthed so finding the fed point could be difficult, but if you have
info of an idiot proof way of loading the tower , I'd be very interested.
I'm not so sure that loops are for Rx only, any thing that can be made to resonate is fair game for
putting RF in to it.

AS for the high Q and high voltages, in the UK the most used part of top band has a limit of 30W,
with a Q of 1100 , that a peak voltage across the cap of 2KV with a bandwidth of 1.5 KHz, but If
you listen on top band in the UK you find most QSO s are centered around 1.933 MHz only offset by a
K or so.
At the full limit on topband there is a section which allows 400W , but thats still only 7.5 KV,
easily handled by some of the vacuum caps available.

I don't think shunt feeding the tower on 80 or 160 meters would
bother VHF equipment. I don't know that there is an idiot proof
way of shunt feeding a tower. However, you can model the tower
with EZNEC and do your experimenting on the computer. Then you
should be able to build the actual feed and have a good chance
of it working.

Very interesting. I had no idea how it worked in the UK. In
the US, we can run 1500W from 1.8 to 2, but I rarely go above 1.9.
I recently worked G3MMT around 1830 kHz and he was over S9 here on
the west coast. I guess a loop could work OK for your purposes.

Richard,

Don't worry about the height, make it fit however you can. Unless you can get the bottom of the 160M loop high above the ground the pattern will have a large NVIS component and will be quite broad also, more oval shape. It will work very well. I've had reports from other's who've tried a short squat 160M wire magnetic loop with excellent results.

I've built some Magnetic loops and in particular The DCTL Loop for 40 Meters . The loop is only 48 inches square and when tuned is oblivious to surrounding nearby structures. It is actually a rendition of the DDRR military loop (Direct Discontinuity Ring Radiator.) I have operated this antenna within my house and it outperformed an external dipole.
I have design ideas for a broadband version of this square loop as well.
I have posted pictures under VE3DDY.

7051. High-Tension Inductance?

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-01-14 16:23:06 UTC
From: Lee- KI4NEJ
Topic: 7051 Message: 7051

Greetings to the list,

As I was driving down the interstate a few afternoons ago, I started tuning the AM dial for the chance of DX.

Much to my surprise, as I crossed under some high-tension powerlines that crossed the highway on the diagonal, instead of RFI, a station from Atlanta came booming-in like I was local. (My QTH is Tampa.)

Was this an example of inductance as I passed under them? I always was under the impression the H/T powerlines were our enemy, due to RFI; now I may have to rethink that.

73,

Lee

Quick story that may relate to this, as a pirate on MW/BC we ran 250mW from a 19Th floor tower bloke and the long wave antenna went across a 270 foot gap to another tower block, we got heard 35 miles away one summer, close buy was a metal fence and railway lines and we think our 250mW TX was getting into those lines, when we got DFed the guys, other pirates came to the flat but could not see the TX, the car auto battery could be seen but was the TX really in that match box - yes it was, and so yes lines of wire from anywhere can induce RF, BTW we lived at the back of Euston Station for UK ref.We once used street lamp post how bad can those be with wire going from one to the next. Something I've wondered when experiencing something like this is if the powerlines were blocking out the stronger station in that direction and allowing reception of the weaker staion not being blocked. The AGC might make it seem like it suddenly 'booms in'.

Just wondering..

Bill

I've seen this many times going under bridges, on both AM and FM bands.
For example, in the San Francisco Bay Area, many stations from 100 miles
away would be Q5 copy from hilltops if not for the many local stations.
You can often copy these "DX" stations under bridges or if you get
the correct shielding from hills. For example, there is a station on
93.1 MHz in at 3000 ft ASL in Pollock Pines, CA that is often heard all
the way to the Pacific Ocean, at least 100 miles away, because there is
no San Francisco station on this frequency.

High tension lines are inconsistent. Some are big RFI sources, others
are quiet as a church mouse.

Hi Jim

Had a look at the pics and am very interested in this antenna. Is there a technical description anywhere? A Google of "DCTL" reveals that it is a much-used acronym: what does yours stand for?

Hi Lee,

It is never clear how an inductive source will react to a receiver .... on one hand the secondary inductive source may add to the signal being received while at another time it may detract from the signal being received .... it all depends on the "phase" of the secondary signal received from the inductive source.

For example ... if you use 2 external tuned loops to assist in receiving MW broadcast stations and you locate them close to themselves and the receiver ... which also has a built in ferrite antenna .... they can be carefully tuned .... not only to achieve resonance ... but to adjust the phase of the signals ....whereby they can either add or detract from any particular signal. Even if there are 2 stations on the same frequency ... one loop can be adjusted to increase the signals of one of the 2 stations while the other loop is adjusted to decrease the strength of the undesired stations ... as I said ...both are on exactly the same frequency ..... the 'phase of the induced signal' is the critical function.

the separate antennas don't necessarily have to be loops .... but you need to be able to adjust the phase of the signals as they combine. The experience of the induced signal from the overhead power cables is a situation in which the induced signal was in an additive phase to the directly received signal ... it could have been the reverse.

Jim

Lee,

I believe what you experienced is re-radiation of the AM BC signal under the power line instead of inductive coupling. I say this because car radios typically have high impedance antennas instead of internal loops like portable radios. My theory is that given the right orientation of the line with respect to the transmitter, and maybe even the distance between transformers, a lot of RF is received by the power line which is re-radiated. This happens with Yagi antennas where the signal is re-radiated by the directors and reflector.

My job for about ten years provided me with a lot of windshield time most of which I spent fiddling with radios. I observed several hot spots under power lines while tuned to a distant station. Of course this was most noticeable while moving slow or stopped at an intersection.

I believe FM hot spots are caused by reflections from surrounding terrine or obstructions. These reflections are much more common and noticeable for VHF frequencies.

Danny,

I was able to duplicate this on the same trip (giving a ride to my daughter) a little later under the same set of powerlines, but approx 5 miles away from the first location.

The station I was listening to was WMLB 1690 Atlanta. Nothing local (frequency-wise) to compete with it. Just6 happened to be bored and was doing a bit of AM DXing on the return trip when this happened. Thought it was pretty cool.

Thanks for the info, Dex. It was a pleasant surprise, to be sure. I was
southbound on the highway and the lines crossed at a shallow angle from
NNW-SSE, so even at highway speeds, I was under them 20-30 seconds, and
just happened to catch the station ID.

The reason I offered inductance as a theory from my very limited
background is that I knew the Pennsylvania Railroad used this technology
to enable engineers to talk engine-caboose, engine engine (of another
train), or engine dispatcher using the trackside powerlines as a medium.

Again, thanks for the info. Still a fascinating hobby, isn't it?

I'm curious to know what would be the results if you try with another car radio from another car? If you can do it, that would be interesting to me. Thanks

7064. Loops and Lightning

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-01-17 16:42:26 UTC
From: kugellagers
Topic: 7064 Message: 7064

Question regarding loop antennas, directional nulling and lightning.

I DX NDBs and AM BCB and have a vertical antenna I built that pulls them in from good distances. It is also is low noise compared to all of the other antennas I have built. If there is a large storm system in the Gulf of Mexico like there was the last couple of days trying to DX in the LW band is nearly impossible.

I am considering adding a multi-turn loop to my antennas. Will a loop make a big difference nulling out lightning? For instance, when there is a big storm in the Gulf of Mexico will orienting a loop in the E-W direction null the lightning crashes out enough or is lightning just too strong of a noise souce?

I live in the Denver, Colorado area by the way so a Gulf storm would be to the south.

John

I use two 85 foot triangular receive loops for BCB and SW listening, one favors N-S reception and the other favors E-W reception. Much to my amazement, I have found that when a thunderstorm is approaching from the west, by switching to my N-S loop the static crashes are significantly reduced. I have no idea if lightning static from an approaching storm is high angle or low angle, or how it compares to lightning static from distant equatorial activity, but it's worth a shot.

Hi John

Yes, the loop will null distant electrical storms. As the storm gets closer the direction becomes broader and the electromagnetic pulses get stronger. The narrower the band pass (tuned) and the better the balance of the loop and feed system the better the rejection.

By the way .... there is some interesting listening to be had as electrical storms get closer. Years ago when I was a kid I built a multi-turn loop which I hung in the attic and connected directly to the mic input of a high gain audio amplifier. eerie whales and whispers can be heard in relation to immanent lightning strikes. They appear to be modulated magnetic fields ..... in any event the loop seems to work as a transducer of some kind connected directly to the AF amplifier.

Of course being in Denver you would need the electrical storm a lot closer than the gulf hi hi.

A shielded loop is reported to be better against noise pickup as compared to a single or multi-turn tuned loop. Many 160M amateurs use them for receive and claim to hear signal below the average noise level on their dipoles.

John / Rob,
For 30+ years I have used a full wave horizontal loop on 40m and
without doubt it is prone to static.
My first experience was on a day with an impending storm and I had disconnected
the radio and antenna but was aware of a ' ticking ' sound, looking around I noticed
sparking between the barrel and center of the S0-239 wall antenna socket.
I promptly dashed out and lowered the antenna to the lawn hi!
That is now the practice in stormy wx, though I have still had a few clouts
whilst disconnecting.

Brian, you probably would have been safer not going out and touching your antenna.

Some place a 33k or 47k ohm resistor across the center feed up at the dipole's feedpoint to bleed off static.

I always disconnect my antennas when leaving the shack. One old ham told me to put the ends in a glass mason jar. I haven't going that far, but it's a good idea.

It might be interesting to use something like Google-Earth or one of the
other satellite mapping programs to trace the power lines and see if they
run particularly close to the AM transmitter site.

I rather doubt that the utility company would be too thrilled to have an
AM station intentionally coupling into their lines. On the other hand, there's
not a lot that can be done to keep a 50KW torch from coupling into a LOT
of things (And, for the worst case scenario, look up what happened when
WLW had a Special Temporary Authorization to run 500KW!).

Yah, very good advice regarding lightning and pretty much any outdoor antenna. All my wire antennas are at DC ground so I avoid the rain and snow static issue, but that certainly does not protect you from lightning!

When a storm is closing in, I disconnect all my feeds and simply hope that the installed grounds at the feedpoint of each antenna look more attractive than anywhere else a lightning strike might choose to go.

My loops are very simple, but very quiet. I use them at times when working 160 meters, 75 meters, 40 meters, and for general BCB and shortwave listening:

typically AM stations are rectified onto the AC lines due to dirty insulators and line connections. The dirty connections are basically acting as diodes. I have a 50KW AM (KNX 1070) here in the Los Angeles area than can get into everything - AC, phone lines, stereo. Even had a 10W FM in high school that would always rebroadcast their signal as the AM carrier got into everything including the wiring and RF section!

That might work for a dipole, but a loop already has DC continuity.

Resistors from both terminals to ground are an even better idea, and would work for the loop too, assuming that the induced voltage is a gradual static build-up relative to ground. (Make sure to size the resistors appropriately so that you don't exceed their power ratings when transmitting.)

If the sparking was across the SO-239, then the lightning must be inducing large voltage spikes across your loop, and the resistors might not have helped. The resistors help bleed off a gradual voltage build-up, not a sudden induced voltage on a nano- or microsecond scale.

After I had posted I noticed the UK call sign.

A "Mason Jar" (brand name, the term used generically, too) is a heavy glass jar with screw on lid, which has a rubber seal, that is used for home canning or "preserves"... jams, vegetables, etc. Most commonly seen in pint and quart sizes.

http://en.wikipedia.org/wiki/Mason_jar

When I was first licensed an older ham I spoke with told me he always disconnects the power plugs and antennas from his radio, putting the end of the antenna coax in a Mason Jar so that any sparking will not set something on fire.

A different email list had a (slightly heated) argument a while back about using a Mason jar to stuff the feedline into, to protect your gear and home from a lightning strike.

If I could summarize, and add how I feel about the subject, a Mason jar is one way to keep the metal parts of your feedline insulated from everything else, when small to moderate voltages come down from the antenna. It's better than leaving the feedline dangling where it could arc and spark and start a fire.

The Mason jar is OK for gradual wind/precip. static build-up if your antenna isn't DC-grounded already. It can probably handle transients in the low thousands of volts due to lightning across town. It can certainly not handle anything close to a direct hit.

The problem with the mason jar approach, is that you need to remember to disconnect the cable and stuff the end into the jar. A permanent protection device would be better.

And you shouldn't depend on either, to protect you from a direct hit. Neither the jar nor an expensive transient protection device will do that.

A better way to protect yourself from a direct hit is to disconnect all feedlines and move them way away, keeping several yards of separation between the antennas (and attached feedlines), and anything in or coming out of your house. And ground everything. Even with that, lightning can find its way from a disconnected antenna into your house if it wants to.

Andy

>> ... One old ham told me to put the ends in a glass mason jar. ...

The fellow was right in saying the jar will contain a spark caused by wind or snow charge build up.

But unfortunately this practice got distorted over time leading many to think the jar would prevent a lightning strike. Now just think, if a bolt of lightning has traveled many miles to find a discharge path is a jar going to contain it?

Provide a good ground path for your feed lines outside the shack!

My first experience with such static was as an early 60s novice who reached for his 75 ohm twin lead to connect it to his 6V6 transmitter during a dry windy snowy day. Lesson learned the hard way!!!!

Greetings to the list-

I've been giving a good amount of 6-strand solid-core 18AWG shielded cable. I was thinking of making a loop antenna with some of this cable, but have a few questions:

1. Good idea or not? Does multi-lead wire lend itself as useful in a loop?

2. What size should I make this loop? Primary interest is NDB's (LW), followed by Military and Utility on HF. I plan on joining the individual strands together, so whatever the radius of the loop is, the actual wire length will be 6 times longer.

Any help is appreciated.

Provided that your Mason Jar did not contain any moonshine in it!. A spark in their would likely cause an explosion!

73,
kevin
kc6pob

When I was first licensed an older ham I spoke with told me he always disconnects the power plugs and antennas from his radio, putting the end of the antenna coax in a Mason Jar so that any sparking will not set something on fire.

Hi !

Check this Shielded loop am antenna;

http://radiomagonline.com/currents/radio_shieldedloop_am_antenna/index.html

It works surprisingly well with a good pre-amplifier.

I've heard of using an NE-2 neon bulb between antenna lines and groung to blead static. So a loop with ballanced line would use 2, one from each wire to ground. Anybody done that? Also, can you do that with a Tx antenna?

The neon bulb is an open circuit until the ionization potential - ~65V for an NE-2 - is reached - above that, it needs current limiting for longevity. It also adds a small amount of capacitance to ground. A solid state receiver would likely suffer some damage at that input level. At 50 Ohms, transmitter RF power levels, allowing some safety, <10 Watts would be safe. Raise that to 600 Ohms, and your limit would be 1 W. A grounded antenna is best. Of course, it beats the old spark gap style lightning protection with a recever!

Most of the old ARRL transmitter schematics included an RFC to ground across the pi-network PA output to protect against output coupling capacitor failure - and the resultant HV DC on the antenna lead. It also would bleed static charges.

David, the problem may be due to the 48/11 turn overlapping balun i.e. the primary to secondary winding capacitance is too high. This will cause the antenna to behave like an endfed vertical and thus reduce the null. Suggest that you rewind the matching transformer on a ring core(AL value 4uH per turn) with the primary to secondary winding separated to reduce the capacitance. The presence of nearby metallic objects can also degrade the null at certain frequencies. This can be a particular issue when using Flag or K9AY antennas in Phased array configurations.

Kind regards

Andrew Ikin

Hmmm.... That's interesting. The 48/11 turns ratio is very close to 48/12, which would readily boil down to 4:1. You could make a much better performing transformer with a pair of 2:1 baluns in series. (or a 2:1 UnUn and a 2:1 BalUn). They can be made with twisted wires, which will provide much better high-end performance due to the lower leakage inductance and higher coupling coefficient.

Chris

Mike
this from the home page answers your question

Description

*This is the Loop Antenna Group to Ask Your Questions, Get Answers and Information about Loop Antennas for improved your Radio Listening and Enjoyment. *

This is your "HOW TO" Loop Antenna Forum to : Get Information, Plan, Design and Build Loop Antennas for both Radio Reception and Transmission.

Loop antennas are used to reduce interference or can be used as compact antennas or for radio direction finding (RDF).

Post Your Question Here! To Get Needed Information and Opinions about a Commercial "Ready-Made" Loop Antenna or help with a home-made loop.

Discussion of this Group is focused on the subject of Loop Antennas. All types of Loop Antennas including Ferrite Rod Loop Antennas; Air-Core Loop Antennas, Shielded Coax Cable Loop Antennas; all types of loop antennas.

Loop Antennas for All Bands : VLF, LF, MF, HF, VHF, UHF, SHF etc. Longwave, Medium Wave (AM/MW/BCB), Shortwave and more.

Hi David

I have been thinking of experimenting with a Flag antenna this coming summer ... Do you rotate your 4x2 mtr antenna? on what MW frequencies does it work best? I am fortunate in that there are no local MW broadcast stations in my location .... everything is DX. I like daytime listening of MW stations in the Duluth and Iron Range area of Minn. .... all of which are at least 100 miles south of me. To date I have been using small tuned loops. Something like the Flag may be useful in allowing me to simply tune between stations without constantly tuning the loop.

Jim

Well one very nice reply, and of course you ALWAYS get the not so nice one that almost say B off, quite rude JIM "Scrutiny of the group has ended" can one not ask a scrunty question! Now I have had two such replies.
I am the moderator of skywaves chat and if someone came to me with such a question, I would do a David Towers reply, not a reply such as the other one, please stop quaking in your shoes Jim, question time is over.
BTW I do make loops - have put up sales - and responded quite well in the past so why make me a non provider and non participant.
I was just wondering how long one subject was going to last, and that's all. Mike.

7105. How many tuning capacitors has each member.

Hi Michael,

Probably about 150 or so. In fact the Butterfly cap for my TRANSMITTING LOOP :-) antenna was in the the junk box. I go it from a Gen Rad Vacuum Tube Bridge that was donated to me, and I diassembled to reduce the volume of the junk box.

Well Mike, I just joined a short time ago. I have been looking for better American AM band reception. Thinking that this would be included in this group, I joined. I had read a lot about ferrite bar antennas and inductive loops, as well as tuned loops, but I have a dilemma with each of these. I want something simple.

You see, I capture my television via antennas...SIX of them pointed in different directions. they are connected via Channel Master "Jointennas" and amplified at the mast. The signal is then split 4 ways. I can watch TV on any of 4 televisions in the house without a rotor. Each TV can watch its own signal from a different antenna. This is outstanding!

OK, next, I tackled the FM radio band. I decided to upgrade my current FM, which consisted of a pair of Antennacraft FM6 antennas and an A/B switch. This was OK, but it was not my ideal setup of any channel at any time from any tuner. I bought a vertical FM whip antenna and placed it at the top of my TV tower...48' above ground. I amplified the signal (a very poor decision according to most FM enthusiasts) and split it to 3 tuners. My main tuner needed better selectivity, due to the omnidirectional nature of the antenna. I bought a Sony XDR-F1HD tuner and had it calibrated and modded. I now receive a station on EVERY spot on the American FM dial, and about 80% of them are VERY clean. OK, now my FM works like my TV does!

Here was my next problem. The Sony collects AM stations very well. I decided that I needed to do a better job on AM because the tuner is capable of it. I decided that I could be very happy ointing a loop antenna in one direction...towards Chicago. This direction is aligned nearly perfectly with my local stations for daytime listening and also with Milwaukee for day and nighttime listening.

Well, I don't want a tunable antenna. I want to be able to tune to a station and have it be received well. I am not a DXer, just someone who likes certain portions of AM radio.

I built a Carver "Ultimate AM Antenna" from internet plans and it works better than the plastic loop that came with the tuner. I built a second one and run them in parallel. I have even better gain now. I know that this 2 loop system is not nearly what a tuned loop is capable of, but I have no hassle of individually tuning stations either.

I joined this group to learn more about the Wellbrook antennas. I read many good things about them and I am hoping that they could be an equal to mosed tuned loops. I am considering the newest version of the ALA 1530s+. If it works as good as other loops without any need for manual tuning, it may be for me. I have read all of the posts on this forum regarding Wellbrook, and most are positive. I simply wish that someone here was in about the same position that I am in. I am really enjoying AM hybrid digital. I can listen to distant, out of market ball games very clearly, but for the most part, my antennas are holding me back.

Any thoughts?

Bill

I've been watching this thread unfold as a typical example of misguided question leading to a variety of apparently dismissive and reactionary feedback. Its the Internet after all ;)

I hardly speak for the group, mostly just a reader, but my take:

- yes it's for MW loops, and other loops, I've built 2 MW loops for reception and want to build another soon
- as several have said, post your thread, everyone will be amenable to your ideas and interests I'm sure
- don't complain about other peoples threads, I think alot of the technophile kibitzing is rather entertaining, I'm sure others do as well
- and about the xmit vs recieve thing, most people don't realize but the physics of xmit and recieve are surprisingly similar, even a receiver builder could learn something from an xmit discussion!

Glad to hear the middlewave group is steaming along as well.

John

hi jim no i dont rotate my flag as i am only interested in transatlantic dx on the mw band here in scotland and as i said in my main question its works great from 530 - 1600 khz and i have had west coast usa ie KOMO KJR and KBRW alaska and even peru but as i said it seems to stop dead at 1600 and from 1610 - 1700 khz its sounds as if there is no antenna in and btw my flag is indoors in the attic and i get a great back null ie i use a dutch station on 1008 or 747 and when the resistor is in use the dutch goes away completely you can see my flag in action here
http://www.youtube.com/user/tvdxrools#p/u and for a indoor antenna it works well but just a bit anoying that it stops at 1600 khz as there is some good dx to be found from 1610 - 1700. thanks for all the other answers re the balun and i will give it a try cheers david ... ayrshire scotland http://band1tvdx.blogspot.com/

Hi David

I have been thinking of experimenting with a Flag antenna this coming summer ... Do you rotate your 4x2 mtr antenna? on what MW frequencies does it work best? I am fortunate in that there are no local MW broadcast stations in my location .... everything is DX. I like daytime listening of MW stations in the Duluth and Iron Range area of Minn. .... all of which are at least 100 miles south of me. To date I have been using small tuned loops. Something like the Flag may be useful in allowing me to simply tune between stations without constantly tuning the loop.

Jim

Thanks...the multiple antennas was a background for what I have done to make viewing and listening easier for multiple users in multiple home locations. My real question was quite well stated at the end. I simply wanted to know if the Wellbrook ALA1530S+ was what I was looking for and if there were any members who had any suggestions, comments or opinions.

I am new here and generally have found it to be too technical for me in many respects, but I find your passive comment about not answering my "4 page question" rather humorous. You asked to get back to reception loops, yet you find my question too trivial to spend time answering??? Yet, you will attack others here for not catering to your desires of what this site should be about?

Bill

7123. The moderators job is to moderate, moderately

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-01-24 15:31:49 UTC
From: alienrelics
Topic: 7123 Message: 7123

My job as moderator is to keep spam off the list, send trolls packing, cool things off if there are misunderstandings/anger, keep the list on topic if it drifts too far, and that sort of thing.

It is -not- my job to decide how long a subject will get hashed out. If people are still talking about something, it is because they want to.

The previous loopantennas list went bust because the moderator ruled with an iron, but erratic and obvious, hand. I try to stay as transparent as possible. I've removed a -lot- of spammers and spam links without any fuss. I've calmed down fusses without fuss. Sometimes I put someone(s) on moderated status and I may block some of their messages, sometimes I am forced to ban someone.

In the current fuss, I've put someone on moderated status so we can get back to talking about all kinds of loop antennas. Transmitting, receiving, copper pipe, ferrite, SLF, VLF, LF, MF, HF, VHF, UHF, SHF, DDRR, UFO (how'd -that- get in there?), RFID, whatever kind members want to talk about.

I won't tolerate trolling. Occasionally we get someone who finds it amusing to push people's buttons. I don't find it amusing.

Let's talk about loop antennas again.

Steve Greenfield

7124. About links to other groups

Yahoo group: loopantennas (2008 — 2012)

7126. Loop from computer flat cable

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-01-24 15:53:13 UTC
From: alienrelics
Topic: 7126 Message: 7126

Not exactly a loop antenna, but many years ago I built a BFO metal detector. The first model had a wooden form with a layer of shielding tape, wire wound around that, then another layer of shielding tape. With a break in the shielding tape so it wasn't a shorted turn.

It drifted like mad. Just moving it from sun to shade, or even from the warm air a foot above the ground to the cooler air an inch above the ground was enough to induce a slow but substantial drift. If I didn't keep retuning, it would drift right out of audible range.

So I took a chunk of largish flexible copper hose about 18 inches long, and took some computer ribbon cable that I sort of twist-rolled and inserted into the copper hose. Rolled the copper into a ring, then soldered the ends 1a to 2b, 2a to 3b, 3a to 4b, etc. then connected to 1b and 50a. I ended up trying a few other taps to get the correct inductance, I think I ended up somewhere around mid-40 turns.

Wow... solid as a rock! From sitting in a cold garage to summer sunlight, to being buried in wet grass in the shade, no more than a few Hz drift.

I used parts pulled out of a pocket AM radio. The tuning capacitor, reference oscillator LC, volume control, and some of the other parts came from the radio. I made a mount for the thumbwheel volume control by cutting and soldering pieces of PCB onto the back of the double-sided PCB I used as the front panel. The front panel I "brushed" with circles by using a pencil with big eraser chucked into a drill press. Rub-on lettering and a coat of clear finished it. The case was a PVC end-cap. The transistors and resistors I bought from Radio Shack.

I should dig it out and try it as a receiving loop. I expect the computer cable's close wire spacing to potentially limit the frequency, but with all those taps I don't see a problem with that.

Steve Greenfield

The dielectric constant of the plastic insulation is also a culprit. However, the HP(whatever) WWVB receiver loop uses a similar method for easing the construction of the multi-turn loop, so what you're proposing will probably make a nice LF/VLF/ELF loop.

Yes I also have a large number of CUBE capacitors, getting the bolts and spindle extension is the main problem, at one time I made and sold {about 30} table top loops, the main frame was from a cut of 60mm {24 inches} round underground tubing and the box was open ended as it was a section of square water pipe, these sold for £25.00
those were the days. Mike.

It would seem it's not in this month PW, could it be it's not a good seller, I am sure it was a military copy, it looked to be about 3-4 foot long going by the very small picture and about 3 foot tall, with a metal mesh under it, so square oblong, it just sat on the balcony, cost if I recall was about £125, surely someone has an old PW with this advertised, yellow pages at the front of PW, was sold by one of the big four Haydon - W&S etc. Mike.

7139. Balun??? for Sony XDR-F1HD?

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-01-25 22:08:23 UTC
From: Bill
Topic: 7139 Message: 7139

I like US commercial AM radio. Or rather, I like talk radio on the American AM band. My tuner is a Sony XDR-F1HD that has been highly modified and calibrated. The tuner accepts twin wires, apparently in a balanced configuration.

I would like to add a very good wideband AM antenna and have been considering a Wellbrook. I asked a question here and Andy from Wellbrook sent me a reply, but also said that he could not provide a balanced output.

I am not an electrical engineer. Is there a balun or adapter that would change the output RG58c(?) of the Wellbrook, or other antenna, to one that can be used by the Sony? How can I make this work?

Thanks,

Bill

Yes Steve that's the one, now please one and all, who in there right mind would pay just under £160 for that, also tell me, 1; how hard to make your own and 2; at what cost, and most of all, how practical would it be.
I used 30 turns over a hula hoop with a 150pF tuning cap and tapping points for 80-10 mts,it worked very well, but being inside a room not the place for RF not even 10 watts, but it worked, cost well under £15.00, hope no one paid £159.95 for this if you did!!!!!!!! own up. mike. M3EMB

I make it about US$ 259.
You can guarantee some poor mug will buy it, The quality of antennas from that company is poor, so
anyone who buys one shouldn't expect it to last very long.

Bill; Yes a balun in reverse would work. 75 ohm unbal to 300 ohm bal. (I'm guessing 300 ohms is the impedance of the Sony's loop but it might be lower since it is twisted wires. Anyone know?)

Question: I heard an XDR tuner and thought the AM bandwidth was too narrow to enjoy listening. You mention modding yours. Did you widen the AM bandwidth or is it OK for you?

Tnx,

Mark

AS far as I know this antenna is manufactured by the Italian "Eco Antenne":
http://www.ecoantenne.it/index.php?cPath=21_25&language=en
I bought this antenna some 15 years ago...but never used it as its tuning (on transmit) was too complicated for me. At that time the only tx I had was a valve RTX by Swan: the Cygnet 270B. So tuning a multiband antenna with a valve tx was not that easy...The antenna is still in a corner of my balcony...

Is the Wellbrook a broadband loop, or a tuned box loop? The Sony employs an auto tuning AM front end - it will add capacitance to the inductive loop automatically to tune the station. If you have a tuned loop out there, the Sony will not be able to accommodate the loop because it will try to ramp down to zero capacitance - apparently out of its range. The Sangean HDT-1x is the same way. Don't put a tuned loop on either one!

What you should do is make a large loop that matches the inductance of the small one. If you get anywhere close, the auto-ranging capacitance inside the tuner IC will match it. Any way you look at it - you WILL have a tuned loop when you are done, it is just that the capacitance is all inside an IC. I've had really good luck with a large un-tuned loop. Unfortunately IBOC is a defective system. HD lock on the only station I am interested in is a lost cause no matter what I do. But regular analog AM is pretty good. It is no GE Superadio, but adequate for most listeners.

By the way - a large loop antenna is balanced by its very nature. The center ground connection, which is sometimes used, is unnecessary because voltage swings around it are symmetrical and AC potential will therefore always be zero. Getting back to the tuner - inside the tuner - there must be a ground connection somewhere on one side of the loop to make the auto-ranging capacitance feature work. Fully differential signal path is very unlikely inside the IC.

7147. Gamma Feed Point...

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-01-26 23:52:55 UTC
From: n6dmb
Topic: 7147 Message: 7147

Hello fellow loop enthusiasts, I have a question or two for you if I may. My loop 5' loop is made of 1.5" copper tubing which has been rolled into a continuous loop by a local metal fabricator set up for such operations. The gap is about 3 inches. An internet source shows a plan for a loop which is very similar to mine except for the relatively narrow tubing. The link will take you to this plan, a plan I offer for illustration purposes only...
http://nmwilliam.tripod.com/mla.jpg
If you take a moment to look at the plan, you will see that the gamma feed location point is placed 300 mm to the right of center, with a spacing of 100 mm. My question to the group is how was that point determined to be the "sweet spot" for the gamma feed location and how do I determine where that point is on my loop antenna? If I understand correctly, shouldn't that feed point should allow for a minimum SWR of 1:1? Using my antenna analyzer, the lowest SWR I can achieve is 1:3. These readings are "without" the capacitor installed. During 1 test, I touched the loop and watched the SWR drop to 1:1. That would bring me to my second question, what gives with that? Will my body act as a capacitor if I am ungrounded? Does it matter to the gamma feed point if the capacitor is installed or not?
Thanks in advance for any advice you might have for me.

Hi Don,

I assume the loop is 5' in diameter and you are planning to use it on 80m.
I have built a number of transmitting loops ... several with the gamma match.
I have never used a formula to determine the structure. I simply did quick
seat
of the pants experiments to get approx dimensions that work. It is usually
quite easy to get a good match near or at 1:1. There is some interaction
between resonance and gamma match settings. (it is easier than getting the
match with a coupling loop).

The loop needs to be tuned to resonance for the experimentation to work ...
without the capacitor the loop is like a dipole formed into a circle and would
probably resonate somewhere higher than 10m. If you wanted to make the
gamma match for 10m the structure would be very much smaller. However
if you want to build the gamma match for 80m ... it will require the loop to
be resonant at 80m in order to build and adjust it.

The 5' diam. loop made of 1.5" copper tubing should work very well on 80m.

Jim

Thanks Bruce. The Wellbrook would be a broadband loop, I believe. It's output is an RG58C with BNC connectors, from what I have been told. I am thinking of perhaps RG6 with BNC on one end and an RF connector on the other end. This would allow for the 75-300 ohm balun, but I am wondering if this will even be close to working considering the 2 different cables and the 50 to 75 to 300 ohm changes. Again, I am no electrical enginner, but I don't want to "shoot myself in the foot" with this either.

Mark, The frequency responce is indeed limited, but that makes this radio quite clear and really doesn't hurt when listening to a phoned-in ballgame or talk-radio shows with a lot of callers. Also, I pick up quite a few HD stations from Milwaukee to Chicago and as far south as Nashville (I live in north central Wisconsin). I believe that the response in AM HD is 20-20k down perhaps 1db at the far ends. My mods were done by RadioX Tuners and to my ears, it sounds wonderful.

I lost a large FM antenna in a storm. With the new and modded Sony (and aligned), I use a Fanfare FM-2G whip antenna mounted 48' above ground and amplified with a Channel Master 7777 preamp. Both the antenna and amplification is frowned upon by vintage FM purists, but this trio picks up an FM station on every spot on the band, and of the 100 or so possible spots, over 80 are very clear and about 50 are perfect. No rotor, about 100 miles max coverage. The tuner has also had an output stage modified for better sound. I never heard it unmodified, but it sounds very good to me now!

Perhaps the Wellbrook loop is overkill, but I really like the AM HD radio I have received, and I figure that the Wellbrook should be a big upgrade over my pair of home-built "Ultimate AM Antennas" from the old Carver design.

Thanks for the replies guys! Any other help, thoughts or concerns would be appreciated!

The big problem with the Wellbrook loop is that it is NOT sold in the United States. I ordered their shortwave model after reading glowing reviews of it in terms of its quietness on the bands. My first one was defective and received NOTHING. After sending it back to Wellbrook in the U.K. (at a cost of over $50), the owner sent me a second one. It too was defective and it cost me another $50 to return it to the U.K. Until he sells it via a U.S. dealer, I would stay away from it.

First, as previously posted, hook up a capacitor. Heck, use a cheap 365pf broadcast variable since you are using an analyzer. I use a cheap var. cap. to get the ballpark resonance and then cut a length of RG8 coax and trim it for resonance. I have several monoband magnetic loops in the attic. Easy and cheap to build.

Connect a short length of wire with a hose clamp and start adjusting for best match, 1:1 will definitely be obtainable.

Using gamma matching you might not get 5 band coverage as is typical using a feed loop. I design my mag loops to cover 2 bands and gamma matching works great.

Nearby objects will alter the impedance of the antenna and affect the gamma match size, also limiting how many bands you can achieve a low acceptable SWR.

You can always compromise, as we do with feed loops, and adjust the gamma match for 1.5:1 SWR across all the bands you intend to cover.

Trial and error, no substitute for that. I guarantee if you tune the loop outside or indoors and finally mount the loop in the attic, for example, you will need to touch up the matching and the tuning for resonance.

The work will be well worth the effort as you will be amazed with the results on receive as well as signal reports.

Keep us posted.

Very interesting! This is the first bad thoughts I have read about Wellbrook anywhere. This has always been a fear of mine and thank you for the post. I find it almost strange that NOBODY in the US builds an antenna similar to this.

Thanks for the opposing view. It is much appreciated.

Fredric,

It is not cost effective to have a dealer in the USA.

The situation as I recall was that after exchanging the Interface units we were unable to get the antenna working properly and you accepted a refund.

You also sent the following e-mail on the 30 Jan 2007

"Dear Andy,

Thanks for your integrity in dealing with this problem. I really wanted this thing to work, but my results were always the same. I did try the old interface with my Yaesu FT-847 ham transceiver. The results were the same, the only thing that attaching the loop did was increase the noise, reception was still impossible. Do you want me to mail back the old interface box as well? Have you heard of any other Americans with these problems? Perhaps the U.S. Postal Service subjects the antenna loop unit to some electronic inspection which blows a component within it? I'm having our local post office check this out.

Regards,

Fred Einstein"

Bill wrote:

Thanks Andy. It's good to hear both sides.

I reply:

There are no "sides" to this. I simply stated a fact. North American buyers are taking a risk purchasing a Wellbrook product because there's no service available over here and failed parts in the circuit cannot be replaced since Wellbrook chooses to encase their electronics in a hard potting-compound to protect Wellbrook's proprietary inventions.

I did not say that Andy Iken was dishonest. I did not say that he made a bad product. What I did say was that I received two items that arrived in Oak Park, MI in a not-working state and were unable to receive ANYTHING. I was totally not at fault for the defective products. I wanted the antenna to work, otherwise I wouldn't have purchased it! I am electronically-capable and am an Extra-Class ham operator who has erected his own antenna tower and Cushcraft Yagi, so I know how to mount a loop onto a fiberglass mast!

I don't know why I received 2 defective products. Perhaps they were X-rayed en-route and delicate components were damaged. My return of these defective items cost me over $100 since I shipped the defective item back to Iken via the SAFEST way possible (Airborne Express) and without complaint and always being polite and considerate of Andy's feelings. He did not inform me that he would not accept items sent via Airborne, UPS, or DHL because they would charge him a duty fee whereas items shipped via the Post Office did not have this duty fee attached. He knew the law, when he corresponded with me, he should have warned me to ONLY ship the returned items via the Post Office - more hassles for me, the innocent victim of these defective products!

Thus, I issued a caveat to North American buyers of Wellbrook products that they are taking a risk. I should not have to be put on the defensive by relating my true and undeniable experience with this product and my decency in putting up with the numerous inconveniences and costs caused by these defective products. Mr. Iken would be well-advised to listen to his customers instead of attacking.someone who dealt honestly and truthfully with him and simply suffered from his company's defective product.

Did Mr. Iken analyze the returned products? What was the problem? That he actually discovered an issue with the returned products would certainly reassure his potential North American buyers that the problems that I experienced have been solved.

From: n6dmb
Topic: 7147 Message: 7156

Hello Jim and Andrew,

Thanks for taking the time to reply to my post. Yes, the loop is 5' OD. The circumference is just under 15 feet. The intended band is 15 meters. Using one of the loop design formulas in the files section, I came up with 1/4 wavelength divided by 3.14 or 15.66' circumference. Actually, I plugged information into ALL the loop design formulas listed and couldn't get any two to agree. Since 1.5" heavy copper tubing comes in 20' lengths, the best the metal fabricator could do for me is the loop I now have, 5 feet across with a circumference just under 15.66'. It works out because this should keep me away from self resonance issues within my desired band. We'll see.

I brought this up a few months ago, but got frustrated with the project and rolled my loop out of sight, behind a shed. My "Buddipole" antenna system works fine. It's time for me to see this loop project through. I will keep everyone informed of my progress.

73,
Don N6DMB

>

Not to dispute Fred's account in any way, but I know there have been dozens of Wellbrook antennas shipped to the US without incident. I was one of the earlier purchasers of a Wellbrook antenna in the US. I think Andy hadn't quite got the packaging fully worked out at that time. Mine arrived with the box containing the interface unit looking like it had been mistaken for a rugby ball. Fortunately, the antenna worked fine.

In contrast, and to support Fred's account of damage occurring in shipping, a couple years ago I bought a ferrite loop antenna from someone who has been building and selling them for many years. When it arrived it was very well packed and the box showed no signs of damage. Yet it was completely dead. I eventually returned it and was told by the seller that this was the first of literally hundreds of these units that had been damaged in shipment. He repaired it and it's been working fine ever since. Just for reference, this package never left the state of origin and traveled less than 300 miles from origin to destination.

Buying anything that has to be shipped to you, you're running a risk of damage during shipping. Ordering from overseas amplifies this risk. It would certainly be preferable if Wellbrook had an agent in the US, but they don't and it seems unlikely that situation will change any time soon. You have to decide if the product is worth the added risk of damage during shipment. Fred's experience, which was certainly unfortunate, I don't believe is typical. The Wellbrook loops are sturdily constructed and have been successfully shipped to dozens (hundreds?) of customers in the US. I see the potential for damage during shipping as just one more thing to consider, not as an overriding concern.

Thanks Bruce. I did not know about the auto tuning electronics for AM. That would explain the untuned loop that came with the XDR-F1.

The Wellbrook is a broadband pre-amplified loop. The signal leaves the pre-amp, mounted at the base of the antenna, as 50 ohm unbal. Soooo - I don't think putting a balun at the base of the auto-tuning XDR will work.

I wonder - Would using the supplied untued loop as a pickup loop for a larger tuned loop work? I will have to try.

Bill, I am in Milwaukee and cannot trigger HD on any Chicago stations - only on locals WTMJ, WISN & WOKY. What kind of mods where done to your tuner?

Mark

Mark,

I am just outside the southwest corner of New London. I am listening to TMJ right now in HD, and For a few hours every afternoon I get WISN in HD also. I also get ESPN AM 1070 out of Madison in HD during much of the day. From Chicago, I just switched to AM 670 and it popped into HD after 8 seconds and is stable. WBBM floats in and out occasionally, but usually is not in HD. At night, I pick up AM 700 out of Cinci in HD. All of this is done with the home made twin "Carver Ultimate AM Antennas". With the factory loop, WTMJ flickers in and out and none of the others lock on HD.

Mike Williams over at radioxtuners.com did my mods. In fact, the picture on his site of the dual cooling fan option is my unit. I begged for and was the first to get fan cooling. I also had the higher feet installed, forced analog, memory extension, disabled LCD backlight in standby, and the treble correction and audiophile output with active filter. Of course, it was also aligned using Brian Beezley's techniques by Mike Williams. I have $370 into the tuner (including both sale price and modifications and alignment) and I am very happy with it.

Hi, Does anyone have any feedback on the differences in performance? I understand that this depends largely on the size, but comparatively how would a 12" ferrite loop perform compared to a 3 foot air core loop?

Thanks in advance,

Jim

I think the rule of thumb is that a loop with a diameter
equal to the rod length will equal or outperform the rod.
Rods have a point only when the space for a loop is not
available.

Hello Jim

Well on the question of comparison, is very relative. I think the ideal would not "compare", but to make an assessment of both antennas. The ferrite loop, although with large 12 ", can generate a large collection of noise as a function of ferrite, taking advantage of only one more field inductance, allowing you to work with the receiver a little farther, without a saturation signal. The loop with air-core in turn will have an excellent collection on its size, but loses its directionality because the longer the loop, the less directional it is. Both antennas are very good, but I think it is not compare income because each one has its feature in particular. www.radiodx.qsl.br Visit the site and see the different kinds of networks that already did, looostick g has only one ferrite rod of 18 cm and has a higher yield than one loop of ferrite with 10 sticks of 22 cm. This is real! The clock high "q" is the setting of the coil. Check out the videos on youtube, search for "Loopstick GE.
I'm sorry for my english.

Respectfully,

Eduardo

As with many things there is a practicality/cost vs efficiency trade off. The magnetic permeability of iron is about 8 times that of air. So if air were made of iron we would all get better performance from our loops.

But magnetic flux is also proportional to area, the "ballpark" point of equivalence might be about:

r^2 = 8

In other words, an air loop will induce more current when it is roughly 3 times larger in diameter than an iron core loop. For your example, 12" = 3*3', so they will be roughly the same. Next I would consider practicality, since air is so much lighter and cheaper, I'd choose the 3' air loop, given the choice.

Of course this is a gross over simplification and I ignored a huge factor: the number of windings. If you want to consider more than one variable things will get more complicated. The other answer, "build em both" is good advice.

I am having trouble making physical sense of this.
Ferromagnetic materials have a relative permeability that is
a function of frequency. The ferrite used for antennas
usually have relative permeability in the range of tens to
thousands. I don't know where you got 8 from.

High permeability cores allow and a magnetic antenna to be
essentially linear, instead of one that covers area. So the
two most general dimensions to be compared are length (of
the ferromagnetic material) versus area of air core loop.
As long as the total wire length is a small fraction of the
wavelength in question, turns count is essentially just an
impedance issue.

There is also the noise contribution of ferromagnetic
material to consider (Google Barkhausen noise).

No, you are the one who is incorrect. Once the material's
intrinsic permeability is >100 or so, the effective permeability
depends on the length to diameter ratio, because of the "air gap"
from one end to the other.

>
> High permeability cores allow and a magnetic antenna to be
> essentially linear, instead of one that covers area. So the

No they don't. Length is only relevant insofar as it affects
effective permeability as mentioned above. Area is still the
important parameter.

Because of its small size, a ferrite loopstick with any reasonable
bandwidth simply cannot have much sensitivity.

Hi,

The thought of John is correct. The catchment area of an air core loop is larger and more sensitive to the local induction of radio waves, than any other variation, with ferrite or not. The distress signal, whatever it is, will always be on the level of noise that already exists and that the radio can detect. Never a small ferrite antenna will have the same ability to detect if it is compared to a 3 foot air core loop.
I set the antenna proposed by our friend K7WW ,Tom (Seatle) , with 42 inches and compared with an antenna that we made using the same ferrite antenna LA 1 Palomar Engineers working in MW. The signal of the air core loop was strongest and clearest ever. All antennas ferrite when they need to raise the received signal to a higher level, require a signal amplifier with very low noise.
All my main listening transcontinental or North American receptions might be possible with the large loop antenna 6 foot air core I made years ago.

Best regards

Denis

Thank you very much all of your feedback. I may build both ferrite and aircore loops. A smaller ferrite loop-stick would be great for travel and indoors, while a larger aircore could be remotely tuned and kept outdoors. Thanks again :)

I agree that the ratio of length yo diameter affects the
effective permeability. I was talking about the relative
permeability of the material, itself. This was in response
to this line "The magnetic permeability of iron
is about 8 times that of air."

>> High permeability cores allow and a magnetic antenna to be
>> essentially linear, instead of one that covers area. So the
>
> No they don't. Length is only relevant insofar as it affects
> effective permeability as mentioned above. Area is still the
> important parameter.

But a high relative permeability material lets a rod shape
(length much bigger than diameter) couple into a volume of
space roughly equivalent to what an air core loop with a
diameter equal to the rod length couples with. This assumes
that the relative permeability of the rod material is much
more than its length to diameter ratio.

Here is a link to a graph of how the material relative
permeability and length to diameter ratio relate to the
effective permeability (inductance multiplier for a coil
wound close to the rod) of the rod in air:

http://www.magneticsgroup.com/pdf/erods.pdf

> Because of its small size, a ferrite loopstick with any reasonable
> bandwidth simply cannot have much sensitivity.

Neither can an air core loop with a diameter no larger than
the rod length. And that loop is harder to fit inside a
radio so that the rest of the stuff in there dies not
interfere with its operation.

"The magnetic permeability of iron is about 8 times that of air."

for steel Westinghouse used Ur=100
for steel General Electric used Ur=500

iron at Ur=8 is way too low

Interesting discussion!

Barkhausen noise seems to be related mostly to the higher intensity field changes. Very small RF changes should not be a major issue here [note that even in the Wiki article, they talk of pulses an dnoise related to very large changes]. The key to building a successful ferrite [or really any] loop is to design it with high Q so that it has very sharp tuning. trying to broadband a loop is not a good idea, because one of the key benefits is high S/N if made properly. If "B-noise" was a major issue, we would not see ferrites used much even in broadband RF Xfrs.

Check Stormwise.com. these folks have really nice 125u large diameter [>1"] long ferrite rods. I made a tunable MW antenna using one of the 13" rods, and it's superb! I used 220/46 litz for the windings. The effective capture area of a loop is dependant on the u factor, but too high a u [mu] will reduce the HF response of the loop making it harder to work at the top end of the band. The noise levels in this 125u rod a VERY low - so low that very weak signals are still audible - often get 3-5 BCB signals overlapping! I can also tune this unit and orient it sufficiently to null out 50kW boomers within 20km of my location. Stacking several ferrite rods and winding about all of them also increases the capture area nicely.

Ferrite materials, if well chosen for geometry/size/dia etc., can have the benefit of reducing overall antenna size while providing excellent performance. The key is in the windings ratio(s) and minimizing inter-winding capacity [use of woven/basket winding, pi [multi-stack] windings, or litz. Then, when tuning, the antenna can double as a preselection device, and pull in the toughies!

(snip)

I didn't mean to imply that Barkhausen noise is a big problem, but it is one difference between ferromagnetic core antennas and air core loops. I think it is inherent in the ferromagnetic effect in any material that has magnetic domains, at all field strengths below complete saturation. But you have to look pretty close to see it in most applications. It does set a limit on signal reception, just as any other source of noise does. Resistance makes noise, also, but it is a limitation only in very low signal amplitude applications.

Dear John et al

all discussion about front end physics of the ferrite

one way to treat the noise is on the output

I use DSP units on my ham equipment but should work fine for MW listerns

I have the West Mountain ClearSpeech little boxie ~ 187 $

also just got and using the new BHI deluxe in line noise DSP which I really like a lot
this unit is on sale this month of 125 pounds, very quick delivery

both these units and others such as TimeWave can be used to effectively remove noise at the audio output stage

best wishes

It's more accurately described as being a large field gradient, and it
is a result of the fact that the changes in the magnetization of the core
are not continuous but instead the switching of the magnetic pole (or rather
dipole) orientation at the molecular lavel within the ferrite crystal
lattice. For instance, in the design of small-signal wideband transformers
the tendency is to use smaller cores, sometimes cores that are too small.
Couple that with the fact that the magnetic field on the core is
concentrated along the surfasce of the core (magnetic skin effect) and you
get a more complete picture of what is taking place with regard to
"B-Boise".

"B-Noise" is worst in situations where ther is no net magnetic flux in
the core. As you get closer to saturation, the number of magnetic poles
remaining to be reoriented is greatly diminished, but then you have problems
with linearity due to the flux saturation.

>
> If "B-noise" was a major issue, we would not see ferrites used much

Oh, but it is, but the problem is that the majority of designers are not
even aware of it. It's a fairly advanced issue that gets very little
attention, if any at all.

I have three papers here that address this, including the 1939 paper by
Barkhausen, which is in German. I've uploaded the one I have in PDF format
into the files section, and if anyone is interested I'll locate and scan and
upload the other two.

I have the West Mountain CLR-SPKR DSP speaker, which I use with my Icom 718 and R75... I now have those two units slaved together and use the MFJ-1708 RF Sense Switch to switch between them for RX and TX.

I previously had the BHI module installed internally to a Yaesu FT-897. To my ear, they are both probably based on the same chip. They both have 4 levels of DSP and the levels have the same "sound". The West Mountain CLR-SPKR is certainly much easier to install, just plug it in.

A huge improvement.

Hi! On the topic of shielded loop, can anyone tell me if the metal for build a loop is important electrically speaking. I've read on this group that aluminum or copper are preferred. Is this because they are non magnetic metal? I have a round piece of metal that I could use to build a shielded loop but it is magnetized metal. Any idea? Thanks
Danny

Hi,

As with any antenna element the material should have the best conductivity possible. The most common of the "best" material is copper. If the antenna element needs to be as light as possible then aluminium is the common choice. There may be better material ... of which I am not aware .... but silver is the premium plus material. However it is quite expensive to silver plate antenna elements .... although I have heard of it. If the material is magnetized it must be some Ferris material .... containing iron .... such as steel.

I am no expert on the conductivity of steel vs copper ... although I have heard anything from 30 times to 6 times worse than copper. Whatever that means .... steel is very useful for its weight to strength ratio and antenna wire is often constructed by copper or silver coating steel wire.

For small loops ... e.g. 1/10 of a wavelength or less the absolute amount of current carrying ability required for efficient operation pretty much precludes the use of steel. This of course also applies to a loop shield which of course is part of the loop element. If you would like to make a shielded loop then it will be small ... and I would stay away from using ferrous metals .... not because of the their magnetic properties ... but their RF conductivity properties.

Jim

Any metal that is magnetic will be very lossy at RF. Forget about it.

Danny
>

Danny,

Copper or AL is used because it has less RF resistance than iron. Also, those two metals won't have a tendancy to rust away outdoors.

The metal "shield" is actually part of the antenna. You can prove that to yourself by touching the metal loop and noticing that the loop detunes when you touch it. So, really, if your loop is mounted "in the clear", it doesn't make a bit of difference in sensistivity or directivity whether it's shielded or not (read more below). If the loop is very near some metal objects, there might be some benefit of having the shield.

A loop that is UN-shielded may have a higher 'Q' because of less distributed capacitance....depends on how it is wound. Having a higher 'Q' usually results in a more sensitive loop, but with narrower (sharper) tuning. The crystal radio boys know this and some have constructed large loops of large litz wire (the right type of litz) for that very purpose.

Because the RF currents run on the "skin" or surface of the metal, You can use copper plated steel for lightness and strength. Remember many of our military whips in the past had that construction. Today they tend to use fibreglass.
At VHF and UHF the plating is frequently silver plated for conductivity but at HF frequencies copper plating is sufficient and even unnecessary.
You could use thinwall copper tubing if you can source some.
Copper becomes magnetic at high current but because , in our case it is oscillating at high frequency, it doesn't show.
I used to work in a copper mine where 1200 amps DC would run through bus bars and you couldn't walk nearby without having your wrist watch destroyed. Carrying a tool box nearby was downright frightening. Fortunately the voltage was low.
I am currently considering building a loop antenna in a square configuration using copper plated steel sections or at least plated where the junctions are. My objectives are lihtness , portability and simple takedown/assembly.

In general, ferromagnetic materials are a VERY poor choice for antennas.
The problem is that, at RF frequencies, the currents flow on the very
outer edge of the conductor (e.g., skin effect). For ferromagnetic materials,
the ferromagnetic properties reduce the skin depth even more, and this
tends to make ferromagnetic materials even more lossy than you'd
normally expect.

There are, of course, ways around this. The common approach is to
plate the ferromagnetic material (and, we're usually talking about steel or
some other Iron compound here) with a higher conductivity,
non-ferromagnetic material. The prototypical plating material is Silver,
due to it's high conductivity, but it's also possible to plate Copper onto
steel (and, this is commercially available as CopperWeld (TM) antenna
wire). Some television lead-in wire, and some telephone wire was also
Copper plated steel.

Failing that, the best wire is Silver, although price usually prevents
the use of that except in very special circumstances (e.g.,
military/government applications, very small microwave antennas, etc.).
Following that, Copper wire is the next best material, quickly followed by
Aluminum wire.

Hi again. Thanks to those who replied to my question. But I did a mistake in that question. Replace "electrically" by RF. In fact, I want to build a shielded loop because the electric noise level here is strong. My question should have been: if the metal I use for a loop is the kind that attract a magnet, will it lower the RF signal or is it unimportant? I'll upload a photo of the loop in the evening.

The good side of my wrong question is that I learned a lot of things from your answer that I didn't know. Thanks for your help.

Danny

Danny It seems you are determined to have a shielded loop. I would suggest you look at a magnetic loop. Do some googling, the available materials, your ability to fabricate come into the picture. I am sure gold might be best but not practical. Silver may be better than copper and so on. Better than what? Litz wire was mentioned. That is what I have in a hula hoop of PVC for a magnetic loop. I could have used copper pipe but this is lighter and works as well. Some make Shielded Loops from coaxial cable!

I think you got some good answers. The answer is best found in antenna books (ARRL books are good) and looking at other successful designs. The topic of antennas I maintain is a science mixed with a little art. Antenna design can go very far into theoretical and mathematics and very fancy spectrum analysis gear to test. At our level and the HF band we are interested it..... there is not much new. Not to say someone might no strike upon a new configuration or design or material no one ever tried before. So research the subject in some good ARRL books and steal.... look at other antennas.

I tend want to assure the results before putting huge effort into an antenna project. I have no desire to invent something new in the antenna World. Clearly there is some creativity in how you make it, which I enjoy. The real joy is making an antenna that works and gives you more gain but best of all is better SNR - Signal to Noise Ratio. It took me a long time to realize that is really the name of the game, SNR. Every antenna has limitations. I still say (sorry know this is a loop group but) the a random wire or variations of it of sufficient length is the "standard" I use. Clearly loops can do better in many areas because it is usually a tuned and directional device, which is also it's drawback.

I don't know what you have tried before but a well installed random wire usually gives good results. The problem is few people install a random wire properly (grounds, baluns). If you have the best random wire installation and it's noisy, than you need to look into getting rid of the noise.

Noise is a big problem for everyone: atmospheric conditions, sun spots and so on, area interference from other stations or bad power transformer and the last area, usually the worst is your home. It is a RFI factory. That is why an outdoor antenna (a reasonable distance from the home) is best (but not always possible). It does not do a lot of good to have the best antenna ever made inside or bolted to your house. Antennas are not magic but amplified magnetic loops (like the welbrook) is the way to go in my opinion for SWL.

Any loop in general has good noise rejection off the sides. I started off with simple unamplified passive resonate loops. They do wonders. You can make two and have one to pick up a signal and another to block interference in an direction, like a phased array antennas. I do this "phased array" with my two MW passive loops. Two loops are better than one.

AM and HF stations use phased arrays to transmit very spacific directional signals in one or more directions while being NULL in other directions. So good luck. George

Hi. Think I will come in on this, 30 turns from a slinky {child's toys} metal type LOL, over a hula hoop, taped via a 150pF cap and fly lead worked for me as I taped around the turns re band, good from RX and TX I used 10 watts as that is what my licence permits. see back pages of Practical Wireless, the guy also had 3 x Slinky's making a long wire and a broom stick vertical, but the loop worked great. They Army did pursue it and there are military vehicles with magnetic loops, more accurately, transmission line antennas, in operation. The military has also pursued magnetic monopoles on Naval vessels. During the Vietnam war the loops replaced the long vertical whips used on backpack radios. It served to help NVIS propagation as well as to save the life of many who wore the radio back pack (the whip no longer gave them away).

The military's interest and use of magnetic loops likely goes back to WWI.

The Military DO use HF loops, the German military for one used loops extensively in WWII and prior to that .

Many NGO organizations are switching to loops for mobile operations as they work best for com's less than 1K - 800 miles or so. Have a look at these supplier's sites for more info!!

http://www.stealth.ae

http://www.qmac.com/NVIS_antenna.html

These are just a couple of suppliers of commercial mobile loop antenna!

I believe Siemens supplies a widely used HF base antenna for airports around the world!! There is also an Italian supplier!

It's Hams unfortunately who have not embraced this technology for some unknown reason which continues to baffle me!

Living in a Townhouse condo , I use two loops a MFJ 1786 for 10-20m and a home made one for 80-40m and they work very well! It's not a beam but it's much better than a lot of the Magic antennae being flogged, which I also tried! The 80/40m one beats the attic mounted short 49 ft 40m dipole consistantly!!

Try a loop if you need a small antenna you will be impressed; it is most over looked technology in Hamdom!!

Cheers!

William -- Mr. Kenneth Patterson is resonsible for development of the antenna he described in "Down-to-Earth Army Antenna," "Electronic" magazine, August 21, 1967. Accordingly, the antenna was designed for quick portability and use in Vietnam. By March 1968 the loop had been used succesfully over there because its high angle radiation made it possible to maintain contact beyond barriers posed by the north/south Annam mountains located inland from the South China Sea. In areas like, for example, the Central Higlands normal whip operation was impractical.

Andrew, please be specific. Which particular model of pack radio used in VietNam war? Your source for this?

Another post claimed German armed forces made use of loop antennas in WW2. I assume this refers to the "Dachantenne" or "roof" or "frame antenna" on trucks and some armored vehicles, such as scout armored cars. I maintain this is NOT a loop type antenna, rather a high capacitance short vertical. I made this case over at the milsurplus list; I will not give all the citations here but perhaps if any interest I can find the old emails. I have German radio manuals and also an instruction book on radio installations on trucks which all go to establish that this was NOT a magnetic loop device. As the German and Italian miltary radio equipment tended to use lower frequencies than Allied equipment, even for mobile use, maybe it would have been to their advantage to use the loop antenna. I recall one interesting thing I read, some model of command (Commmander's) tank using the WS30 transmitter (1 - 3 MHz) initially used the frame antenna, but replaced it later with the "Sternantenna" or "Star Antenna", a short vertical with loading hat looking like an partially openend umbrella, without the fabric. I assume the reason was that antennas were frequently damaged, and the frame antenna simply was too difficult and expensive to frequently replace.
I note, however, the replacement vertical was a 1 for 1 replacement; no difference in transmitter loading circuitry was required.
Oh, yes, also: if you cite that article in the U.S. Army magazine, called, I think, "Communicator", that article is without factual basis - it also is based simply on the author's erroneous and unsupported speculation. -Hue Miller

7195. Military Loop Antennas

List,

The PRC-77 military radio and photos are here of the radio and antenna parts.

http://en.wikipedia.org/wiki/AN/PRC-77_Portable_Transceiver

and http://www.associated-ind.com/pdf/ANPRC77.pdf

The PRC-77 transceiver used a 10 and 3 foot long vertical antennas. I was in a Signal unit in Korea, 69-70, and we shipped cargo ship loads of Signal equipment to the ROK army in Vietnam. None of the radios had loop antennas that I know about and I'm not able to construct such an antenna. If a loop existed, tell me what they looked like and how they were made. The second site shows the individual parts of the antennas. I calculated both antennas for 1/4 wave depending on the low or high frequency used, 30-76 MHz.

One of the guys on my sites who used them in Vietnam said the PRC-77 had a range of 10 miles at Base Camp but only 1 mile when the NVA and VC were shooting at them and were heavy with a second battery pack.

Are we talking about "short" loops?
I think in WW II they were used as direction finding / navigational antennas.
It seems rather odd that someone would use them in mobile service.

The requirement of for tuning (the antenna itself, not the coupler / transmatch)
and high voltage may be the deterrent for usage in ham TX "service" on HF.

HI all
I've just built a large loop for 80 mtrs, I've use OH7SV's spread sheet, and my attempt looks to be
500 KHz too high.
I'm using LDF4-50 coax and a 100pF doorknob capacitor for tuning. The circumference of the loop is
12.15 mtrs, I used a diameter of 14 mm. that resonated at just under 4MHz.
I increased the length of coax by 100mm each side of the capacitor and it reduced the resonant freq
by 50 KHz.
The bottom of the loop is about 1mtr above ground.
I need to get this sorted quick as the XYL went a bit ape when she saw this loop had appeared in
the middle of the garden, she'll go a bit more as I'm now using the pipe the rotary clothes line
goes in to hold the loop up while I'm playing with it.

Here's something useful I' found:-
LDF4-50 is a tight fit into 15 mm Copper pipe

A bit more

I have got the loop to resonate at the moment at 3.73MHz,by adding about 1 mtr of 15 mm Cu pipe.
But the vswr is 3:1.
I've use a loop of 141 semirigid coax with a OD of 770 mm at the cold end of the loop

Any suggestions would be appreciated
TIA

You will need to experiment with the feed loop diameter and spacing/coupling to the main loop. Perhaps squash the feed loop in to an oval making sure the feedloop is very near the main loop. If the SWR goes down increase the size of the feed loop and watch SWR. Also, the loop will need retuning so a variable capacitor will be necessary, or a small length of coax cable used as a capacitor in paralle with the doorknob capacitor. Trim the coax stub capacitor for lowest SWR. It is an iterative process but you will be able to get 1:1 SWR at resonance.

Thanks Andrew, I'll try that in the morning.
Is there any advantage in the feedloop being in electrical contact with the loop, ie
the centre point of the loop connected to the ground side of the feedloop ?

I have used both although lately I find it simpler to keep the loop isolated from the main loop. Easy to do if the feed loop or main loop is insulated.

Since the feed loop efficiency is not as important as the main loop feel free to use easy to adjust mechanical clamps so you can lengthen or shorten the feed loop size without the need to solder.

From: capntripps2000
Topic: 7197 Message: 7202

Richard,

Another note on using feed loops. The lower the loop is to ground the larger the feed loop will need to be. Ground proximity has an effect on feed point impedance as well as proximity to other nearby objects. It is another reason why I like a mechanical clamp for adjusting feed loop side. When I build and tune my loops, generally in the basement or in the yard, I need to readjust the feed loop size and shape when I move the loop to its final destination, usually in the attic or in a corner of the yard hidden among trees near a fence.

I also use toroid with inductive for impedance transformation at the feed point. I built a box with 12 position switch to select the appropriate tap on the primary (coax) side of the toroid while the loop side remains the same at 2 turns. The toroid is a T240-61 core. This matches the impedance over a wide range and I always achieve a 1:1 SWR using this method. The toroid limits you to power, generally 100W for this side core. More information on this can be found at http://g0cwt.co.uk/magloops/

As you can see at the above site there are several ways to effectively feed a magnetic loop.

Andrew

From: richard
Topic: 7203 Message: 7203

Thanks for the help so far
I'm now in the position of 1:1 VSWR at 3.7550 and 21.4 KHz usable bandwidth to the
1.5:1 VSWR upper and lower points.

I've had it mounted while working on it on the rotary clothes line stub so its about
4.5 mtrs away from the tower.

Am I correct that the directivity of a mag loop is the same quad element,

ie radiation pattern in line with the loop facing you so you can see the whole
circumference of the
loop .

Another question,
Weather proofing , as the capacitor is at a higher impedance , which is better, to wrap
with self
amalgamating tape, or to paint it with a non conductive paint ?

Looking at http://g0cwt.co.uk/magloops/new_page_5.htm, at the feed point I'm using the
feed
impedance would be 5.5 ohms,with the feed loop matching to 50 ohms ish.

Is it better to treat the feed loop as balanced , I do have a balance to unbalanced thing
made of
43 turns of RG58 coax wound on a 50mm glass fibre former.

Sorry for the some what basic questions , but I've spent the last 30 years playing with RF
where
3.5 MHz was like DC with a bit of ripple on it.

OK now I'm confused.

If I align the loop with the axis in line with the tower, I can't get a VSWR less than 3:1, If I rotate 90 degrees it drops down to 1:1

I've played with loop yagis ,. why should what basically is the driven element change its behaviour
when capacitively shortened and used on its own ?

??

A so-called "magnetic" loop is by definition small enough that the
current is uniform around the loop. The current in a 1 wavelength
loop as used in a quad beam is definitely not uniform. Small
loops are "end fire" and quad loops are "broadside". The null
of a small loop is perpendicular to the plane of the loop.

It sounds like you are relying on coupling to the tower to make
your loop tune.

Generally speaking a full size loop or 1 wavelength (usual in a quad element) has maximum reception broadside or perpendicular to the plane. However small loops (usually defined as 1/10 wavelength or less) have the null broadside to the loop or perpendicular to the plane. The reason I say 'generally' is that when the small loop is tuned the pattern is shifted to some degree.

Generally speaking (again hi hi) the answer is yes. Imbalance in the loop feed does affect the radiation pattern to a degree. So for example ... if one is designing a loop direction finder then care is taken to balance in all aspects, the feed system, symmetry in construction, and the use of a shield. In other uses ... such as an efficient small loop for xmit/rcv ... balance is not critical.

Thanks Rick

that makes sense, I hope the loop tuning is not being effected by the proximity of the tower, as
its normal place when I'm happy with it is about 30' away from the house and tower.

The pattern is less affected the lower the frequency AND the lower the loop is in height.

My 1/4w circumference 80/160M magnetic loop is 1 meter above the ground at its lowest side and the 4NEC2 models show the patter is very oval in shape, which makes it good enough for general non-directional use. Raise the loop higer and the patter does start to become more directional.

Thanks Jim

I'll fit the Balun on and see if it make a lot of difference, The coax feed to the loop will be
buried, so it would be nice to get as much RF off the braid and to protect it from the XYL with
the mowing machine.

Its definitely working well in its current position as I'm seeing S9+ signals with it.

On YOU TUBE one can see this idea, you take a long envelope and cut off a short end, cut two bits of cardboard to go inside, paste on some tin foil one one side of each and with a blank side over a tin foil side slide one bit of cardboard over the other, two wires being taped to each tin foil side. I recall seeing how this was done in a WW2 film, re clandestine radio reception, I think the POLES did it plus the DUTCH using KILM tins. Mike - Suffolk.

Hi Sid,

My antenna is similar to his 7 - 14 MHz Octagon radiator antenna, but I used 7/8 inch Heliax for the radiator, and a junk-box butterfly cap (from an old RF Bridge for Vacuum Tubes).

I would not use PCB for the butterfly cap. The currents involved are large, and might be too much for the foil. Also, you do not want to expose the PCB dielectric to fields. Even the better Microwave PCB dielectrics are probably too lossy. SO, have the PCB double sided, and put a VIA or two between the outer foils. Possibly Polyflon materials could be used, but now your talking bucs.

I have seen other hams who have used telescoping tubing for the capacitor, with a teflon, or cross-linked polyethylene (do not get black!) dielectric tube inbetween built similiary to the trombone trimmer ON4CEQ shows. Polyethylene, even when cross-linked is a very good dielectric. For a single frequency cap, a RG-213/214 Gimick capacitor would work just fine.

Take a look at Ben G0CWT's wire magnetic mobile loop. I built one and it worked great. If you run it from your camper other stations will think you're running a dipole. Very effective antenna.

Hiya
You could try what I've just built and works well, and you can disassemble it for packing it away.

Have a good groop thru your junk box , you will need a capacitor that will cover 80 ~100pF , you
could use a fixed door knob capacitor which would give you just under 8KHz of usable band with a
lowish vswr, or a combination of fixed and variable caps.
You will need a 5 mtr length of LDF4-50, and a yard of 1/2" copper pipe.
Now strip back the outer PVC on the LDF4-50 to expose about a foot of the copper at each end.
You will find the copper pipe will slide ove the LDF4-50 hardline coax.
cut the 1/2" copper pie into two sections and fit the capacitor in between the two bits of copper
1/2" copper pipe,
You can form the loop by sliding the 1/2" over each end of the LFD4-50.
Its a tight fit, and you might need to ease the ridges on the LDF4-50.
You can either tune the loop with capicitors (variable), or use a fixed capacitor and alter the
length of the loop by sliding more or less pipe over the coax.

There is a spreadsheet program on OH7SV's site, look under 80 mtr loop .
the coupling loop is 0.3 mtr, about a foot.
when you want to pack it away just pull the thing apart and stow, you could if wanted straighten
the coax out first, then you have a tiny stowage space.
A 5 mtr loop of LDF4-50 is nearly self supporting, so I don't think your will need a frame.
If you feel a frame would be nice, use the glassfibre 1/4" dia rods that are used to support small
frame tents, most camping stores have them, tie with either nylon or string.

If a 5 mtr length of LDF4-50 is awkward to stow, yoiu can allways cut it in half and use a piece of
1/2" copper pipe to join it when in use.

Thanks to Cor making mention of Foxit, I'm now able to read this document.

This is a substantial piece of design work, and the author went much further back into loop antenna history than we would normally see in latter-day publications on this subject.

The cross-connection at the gaps is very curious, and he's gone to a great degree of effort to minimize common-mode interference.

Through the years I have been searching for background material on antennas and radio reception. After a while a number of names or callsigns become familiar, because belonging to an author of interesting articles. So on my computer I have a directory named Bryant_Bowers_Connelly. In that directory I have a collection of in my opinion of very good material with theory and practical advice on antennas, cables and baluns. So whenever I saw the name John Bryant somewhere I knew it would made sense to retrieve the information given. I have seen his name mentioned in this group on a regular basis.

Therefore it came as a shock to find the following message on RadioBanter.com .(http://www.radiobanter.com/showthread.php?t=149680)

DefaultRIP - John Bryant, a great DX'er

_____

To my DXplorer friends--

It is my sad duty to inform you that yesterday John Bryant fell from a ladder and received injuries that resulted in his death this morning. As you are, I am shocked--John was not only one of my best friends but also a writing partner and travel buddy. As I find out details on arrangements I will keep you posted. Please raise a glass to John--we have all lost a valued friend and colleague.

Harold Cones
(via Horacio A. Nigro, DXLD)

I wanted to share this with you.

Topic: 7227 Message: 7227

Once the 100 year snow in Philly area disappears, the first planned spring antenna project is installing a FW hor loop cut for 3.5 Mhz (287 feet circumference). Shape is rectangular, height above ground is 45 feet. My two story colonial house is within the front part of loop rectangle (approx 164 feet worth of total loop circumference). Closest distance from any second floor room to a point on this 164 feet portion of #16 AWG, pvc covered, wire loop is 20 feet. Planned transmission line interface is 70 ft of RG59, 75 ohm coax along ground, with a balance coax balun (12 turns of coax on 4 inch diameter form) at point where coax connects to 45 ft of #16 AWG stranded speaker wire (estimated surge impedance is about 80 ohms). Top end of speaker wire connects to horizontal loop. If any of my questions have already been addressed, please point me to applicable message number. The Yahoo Group keyword search function is not very useful. 1. Max RF power is 150 watts rms. Will the RF level on second floor be below acceptable personnel safety limits for all transmission modes? Per article at this page : (http://www.arrl.org/news/rfsafety/exposure_regs.html) "At HF, 150 W to any antenna would be unconditionally safe when the antenna is 10 meters from areas of exposure--with a significant safety margin." Unfortunately, I'm about 10 feet below this limit. 2. I plan on building the balanced line current measurement unit described here. (http://users.tpg.com.au/users/ldbutler/Line_Bal_Test_Meter.htm) to measure the transmission line current balance. How much a per cent mismatch between line currents is considered okay? i.e. no significant transmission line radiation which affect antenna radiation pattern. 3. What is the simplest measurement technique for measuring the SWR dependent losses of this transmission line system? Using coax for the last 70 feet of transmission line interface because it is close to ground and house exterior is aluminum siding. Have seen comments which recommend keeping open wire line away from conductive materials. I have a resistive return loss bridge and signal generator, to check the SWR at the ground end of speaker wire. The SWR at transmitter end of coax can also be measured with this same bridge. A LC (or switched to CL configuration) matching unit will be used between transmitter output and coax to antenna. An SWR meter (directional coupler type) will be between transmitter and matching unit. Hopefully, these three SWR measurements (1. coax end of speaker wire, 2. transmitter end of coax, and 3. transmitter end of SWR meter when matching unit is adjusted) will be enough to quantify the "SWR-dependent" loss of transmission line interface. The purpose of this exercise is to help decide if speaker wire should be replaced with windowed ladder line and RG59 replaced with a lower loss type coax to increase effective radiated power. Larry, W2HHV

Generally, I don't think much of Harbor Freight Tools. However, they had a one-page ad in today's newspaper with a bunch of coupons, one of which was for a free 9-LED flashlight. They also had a 20% off any one item coupon. I went to the Harbor Freight about 4 miles south of me and looked around. Since my shop has just about every sort of tool I can imagine needing I didn't expect to see anything of interest. However, I spent a good deal of time looking this item over:

http://www.harborfreight.com/cpi/ctaf/displayitem.taf?Itemnumber=99736

Anyone who builds loop antennas knows exactly what this is good for. The number of dies is limited to three sizes. But, I'm going to look in a local junk yard for pulleys and see if I can make my own for bending 1/2", 3/4", and 1" copper pipe. It's a whole lot cheaper than a Greenlee or Rigid hydraulic bender, and you can do any radius you desire by adjusting the centre jack screw.

And I did get the free flashlight. It has a metal body, which is far better than what I was expecting, plus it included the batteries. And it's bright to the point where you don't want to look directly at it.

Yes, the do have good deals. You just have to realize and accept the quality of the parts as you put your money down. Once you do that, just use the piece of equipment without complaint. If you wanted the Craftsman guarantee, you would have bought from Sears/K-Mart/OSH (Orchard Supply Hardware).

I stopped in to Harbor Freight a few weeks ago pick up some stepped drill bits for a project and also ended up buying a heat gun, with two temp ranges - warm & hot, for $9.99. A comparable price is 30 to 40 dollars more. I've always wanted one for personal use when working with heatshrink tubing as some of the tubing I was starting to work with outgrew the capability of my 35w soldering iron. (I used to have access to one when I worked in a company facility. I haven't had access to one for over 5 years since I work from home or at a client's facility.) A heat gun can also be used to preheat the solder paste when working with surface mount parts and also when desoldering ICs.

Hi Richard -- I just read your request for info!!

Due to antenna restrictions, I use a homebuilt 6 ft dia loop on 80/40m inside my aluminum clad garage alongside my car and still able to work out almost as well as others with average dipoles! The car will shift the tune point a bit and probably doesn't help much but it does work! The Q will be affected more by the loop material and resistance of the loop/cap assembly than anything else!

If you have to mount the loop on a mast I'd go for the aluminum mast, I use one myself and it doesn't appear to affect it!

BTW -- a good cost effective loop can be made out of 7/8 inch Heliax, which is what I used. This stuff can be found used at most fleamarkets for next to nothing as many of the cell towers are removing it due to new equipment configurations! My loop uses about 19 ft of Heliax and a dual gang air variable cap turned by a DC motor feed over the coax from a MFJ loop control box! Very simple but effective!
I also use the MFJ loops, the 20-10m one is a good performer and easy to use!!

If you would like more info on how to make one for 160m Google "vk4amz" as he has a nice web site describing his 160m loop. I've seen his and have heard him on the air. He does extremely well compared to other stations using full size antennae!

Main thing is don't be discouraged, just go ahead and try it as I guarantee you will be impressed by the performance of a well built loop!

Cheers!

Well my loop is up in the garden now, and works surprisingly well.
Its just under 4 mtrs dia, made from LDF4-50, which interfaces with 15mm Cu water pipe for the
end terminations ect.At the moment I'm using a single 100 pF doorknob cab, which centers it on
3.755 MHz.I now have the motor to drive a 100pF vacuum variable cap which is rated at 10Kv ,
that'll allow 400W to be used.
Still trying to sort out the cap mounting which has to be rock solid, or the belt drive to the motor
will slip, and getting a position indicator back in the shack.
--
Best wishes

Richard Bown

I've bought a few H-F items of note, most recently a 12V booster/power supply for ~$30. It contains a 12V 17 A-Hr sealed cell and a 120VAC recharger. Great for DXpeditions... or when you go out and find you left the lights on your car on last night - and your car won't start.

Totally off topic, a large digitally locked 'executive safe', actually, a firearms safe, they regularly have for $140+ makes a great 'dangerous item' holder. I store homebrew ammo in it, but others have their electric hand tools, solvents, paints, etc, in them, too. Not fireproof - or gas tight - they will keep little folks out - and contain any flammable items, thus not causing an explosion. As has been said, one takes their items with a modicum of chagrin. Of course, they do carry a few name-brand items - and even a few USA-made items, too.

Okay, I'll come clean... there is an Ecuadorian restaurant in the same strip mall as the Birmingham H-F. Their Mex food is fantastic.

A fellow on another list sent me this URL for a similar tubing bender
made of wood that appeared in Mother Earth News back in 1980:

http://www.motherearthnews.com/Do-It-Yourself/1980-09-01/Homemade-Tubing-Rol
ler.aspx

Now THAT'S inspirational. I can get that article next time I visit the
university library as they have it bound on the shelves as well as
electronically from Mother Earth News.

7243. Insulated wire loop under roof tiles

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-02 05:17:33 UTC
From: billcurd
Topic: 7243 Message: 7243

I'd like to put up a multi-band HF loop antenna (preferably covering 80m-10m transmission, and full 3-30 MHz reception) but have some constraints and would appreciate any advice. I have a Kenwood TS-50 and AT-50 in my second story home office.

The exterior walls are stucco over ungrounded chicken wire and the office has a lot of RF noisy computer equipment. Attempts at HF reception with an indoor antenna have been extremely poor. Because of the RF noise, the chicken wire, and AT-50 not having a balanced output, I'm thinking of running coax through the wall to a balun outside on the edge of the roof.

No quality ground is available (just poor conducting desert soil down one floor).

The XYL wouldn't approve of wires along the fence line or in the yard.

So, I'm thinking of laying (hiding) insulated stranded copper electrical wire directly under the tiles of my roof to roughly form a rectangle. Just below the ridge line, down the slope, and along the bottom tiles. With a couple of small jogs and circumference of approximately 40m.

Would it work?
Any voltage or current dangers to the house (I haven't seen anything about voltage and current patterns in a loop antenna)?
Capacitance problems laying directly on roof?
Impedance ratio for the balun?
Any better ideas than 14AWG insulated stranded copper wire?

If I used cable that was 2-conductor - admittedly spaced very close together, what if I connected it as a double loop totaling 80m?
Or with other cable, even 3 loops or more?

BTW, my other choice is something small on top of my patio roof (I'm thinking of putting a 2m/440 Jpole there). A Tek-tenna? Remember: no ground handy. I have a manual MJF antenna tuner that handles balanced line but would prefer automatic tuning.

Between the HOA and XYL, anything has to be pretty small or hidden. Thank you in advance for any feedback.

If you want to reduce noise get the antenna as far away from the house as possible. You have a fence, good. Run #24 magnet wire around the perimeter of the fence. Your wife won't see it. Demonstrate that to her. You could run it through the air and it wil be nearly invisible.
You'll need a counterpoise, run it from the base of the fence away and along the ground.

If you truly want a ground independent antenna a magnetic loop will do great. See:
http://groups.yahoo.com/group/loopantennas/photos/album/790192499/pic/list

AA0NI did a great job with his loop considering his obstacles. You could lay that loop on your roof but it will do much better vertically mounted.

Also, give this a look:

http://www.aa5tb.com/loop.html

Is your yard surrounded by trees? Any special landscaping? Covered patio? You would be amazed at what you could do with stealthily hidden wires/loops. Keep the loops vertical if at all possible to reduce your ground losses.

SGC has a very interesting document on stealth loops worth reviewing.

http://www.sgcworld.com/Publications/Books/stealthbook.pdf

If you could remote mount your tuner you an have a more efficient antenna situation.

Easier and cheaper to make up a 283Ft wire loop, fed with 300 ohm slotted line of a convenient length running from the shack to the nearest point on the loop. No balun needed but you should either treat it as a balanced line terminals feed or cheat and run one side of the ribbon to the centre pin of a PL259 and the otherside to the earthy wingnut. Hang it horizontally and fire !!! Omni directional and all band 10 - 80. Strap the feeders and tune against earth for 160m.

My shack is on the (USA) second floor with no short path to earth. Under the carpet I have laid overlapping aluminium foil widths and one leg of my desk is compressing down on a piece of chrome plated brass plate, in contact with the aluminium surface about 7x4 inches, with a drilled hole and solder tag connected. A short length of braid goes from there to the earthy wingnut on the back of my tuner unit. I have no idea what an 8 foot square plate, 8 feet above true ground exhibits by way of capacitance to earth, but this idea gives me a fair artificial earth. This is used in conjunction with a large wire loop, resonant in the 5 MHz band.
That took me from Cornwall UK to Long Island NY last night on 5371.5 kHz, with just 100W. I suggest that an auto tuner on the end of a piece of coax cable coupled to a large wire loop of 283Ft (thin wire OK) would do you proud. Baluns will not change in ratio as your band changes find differing impedances flicking from band to band. I have tried a 4:1 balun in the past but it warmed up with 100W transmission, and hated the bands above 20M. Wires under the tiles will be close to house borne interference, TV timebase racket etc. Good luck Bill. 73 de Mike, G4HOL

From: VK1OO
Topic: 7248 Message: 7248

Hi,

I'm building an Arduino rotator controller and it occurred to me I could also control the motor drive for the variable capacitor on my magnetic loop. So, the question is what protocol set to use for controlling the loop? There are plenty of such for controlling the azimuth/controller, but I've not seen any for loops. Is there something in common use, or de we need to define a set here?

I've got an 80m horiz loop up, was feeding with 300 twinlead, just switched to 450 window line. If you connect to tuner's balanced terminals, it does go through a 4:1 balun on most tuners. I'm running mine through a seperate balun, right before the tuner, then into the coax connector on the tuner. That way I can disconnect and go straight to the radio for MW, which my tuner won't pass. Saves having to tune while doing a little swl, too. What I hope to do in the future is modify the tuner to isolate from ground and put a 1:1 balun between the tuner and the radio, but not sure how much difference it would make.

It's omni directional, but the higher you go in harmonics, the more lodes it develops, with some pretty deep nulls between the lobes, so you could wind up with your target area in one of these nulls depending on orientation.

As far as the super loop goes, I'm thinking of making one, but not sure how I could string it so that the lower section would not be in the way. I've heard good stuff about it.

I want to improve my 40 meter signal. I have room to put up either a 40 meter or 80 meter loop. If I put up a 80 meter loop that is cut to a size that is 2 times my desired 40 meter operating frequency, will it perform any better than a 40 meter loop cut to the desired frequency?

I would prefer to feed the loop with coax and from what I have been able to read, I could do that with the 40 meter loop. Can I do that with the 80 meter loop and have acceptable swr? Any real advantage of putting up the larger loop for operating only on the desired 40 meter freq?

Thanks for your comments.

Hi Bob

I assume you are talking about a horizontal loop. If so, then the 80 mtr dimension will work better on 40 m. The reason is that a 1 wavelength loop has maximum radiation perpendicular to the plane of the loop ... which in the case of a horizontal configuration is straight up. A 2 wavelength loop will have end fire radiation ... which will produce an improved vertical angle of radiation. If the loop is configured vertically ... e.g. in a triangular configuration ... the 40m loop is an excellent performer ... and a good match for a coax feed line.

>I would prefer to feed the loop with coax and from what I have been able

Yes, the 2 wavelength loop will not present a good direct match to coax. No doubt you will be able to couple to the end of your coax feed line with an trans-match at the xcvr .... whether the loss in the feed line is acceptable is up to you. Perhaps someone else will address the feed problem to a 2 wavelength loop.

80 metre loop will give you more gain than the 40 m one. You will really enjoy the signal reports you get. COAX SUCKS ! (Use either an autotuner on the end of the 283 Ft loop or run some 300ohm slotted twin to a tuner in the shack. The length isn't really important, as it should be regarded as non-radiating and on the other side of the coin noise cancelling for Rx.) You will not get multiband performance with coax. Your 283 Ft loop will work 80 to 10 metres with ease on twin feeder. By the time you get to use it on 28 MHz it is 8 wavelengths and has some high gain at very low (horizon kissing) angles of radiation.

I once had a full size 80m loop is a triangular formation and feed it a little away from one of the corners. Interesting as it would be classified as a horizontal loop. I fed it using a quarter section out of 75 coax then mate it with a 50 ohms to the shack.
It never let me down as I could use the turner on any frequency I wanted to bring the swr down in the shack end.
I am not sure if by doubling the length for 40m can apply as I think it has to be an odd harmonic as in the case of a dipole designed for 40m is a 3rd harmonic on 15m.
In any case the antenna analyser will tell of the status but get the swr to a 1.5:1 on 80m then work from there.
The apex in my case was 50 feet and the triangle two corners were 20 feet high.
It was my favourite low band antenna compared to a vertical as it doesn't seem to pick up a lot of noise and static, which I suppose a loop been in close formation electrically.

Hi All
I have now got my 80mtr mag loop tunable, its 12.5 mtrs dia made from LDF4-50 and the top metre or so from 15 mm copper tubing.
I've used a large Russian 5 -100 pF Vacuum variable and motor driven it. I've used a 810:1` geared
12V motor and belt driven the Capacitor from it using 10mm timing belts, that gives about 1.6:1
additional reduction to the cap. I've used a timing bet to drive a 10 turn pot from the motor with
a 3:1 reduction.
So remote driving it from the shack is easy now. The intention is to switch in a 390 pF door knob
cap in parallel with the cap to cover top band, calculation gives 1.85 to 2.00 MHz.

What has surprised me is it also covers 40 mtrs, and making comparison with the shortened 40 mtr/20
mtrs dipole at 25 feet above ground,(its the design that was in Radcom a few years ago, thats
basically a 20mtr dipole with a trapped shortened 40 mtr extension·)
With the voltage ratings on the capacitors I should be able to run 400W into it.

I found that the cheapest source of hard polycarb 10 mm are the white plastic chopping boards sold
for kitchen use.

Hi Richard,

You certainly can. That is in fact how one constructs a multi-band Quad antenna.

yes that kinda thing Kevin , I was thinking of something covering 18-24 MHz.
Maybe orthogonal as Chris suggested.
With that design, I'm guessing that there maybe a fair bit of interaction between them, hence the
need for preamps.

Maybe give it a try, I thought maybe worth asking as there's no point in try to invent the wheel.

Thanks

Hi Richard,

As an addendum: concentric full self resonant loops are of a manageable size in the VHF range ... as you move into HF they are commonly used from 14 mhz to 28 mhz .... and rotatable. At frequencies below 14 mhz they are very large and almost always single fixed loops.

Small loops .... less than 1/10 wavelength are by definition non resonant (unless they are tuned) and putting 2 loops on the same axis makes little sense .... the exception being loops used for direction finding ... in which case they are mounted at right angles to each other. the reason for using 2 loops is that the null can be rotated electronically in the radio room instead of actually mechanically rotating the loops.

Hi Jim the reason for thinking of the concentric mag loops , is The mage loop I've just built
4mtrs in diameter tunes from 40 mtrs thru to 80 and with an additional cap switched in will cover
most of top band.
I'm OK for antennas for 14,21.28,50,70,144,432,1296,2320,5760 and 10368 MHz.

I have a hole for 18 & 24 MHz, I can resonate the feeder on the 7/14 MHz dipole but its a pig
and takes a lot of fiddling with the ATU to get it right.
A 1.2 mtr mag loop tuned with 5 -20pF would fill the hole, and thats why the questiopn of putting
them concentrically.

HTH

Hi Richard,

Putting tuned magnetic loops on the same axis is a different story. I assume that doing so is for reasons of access or convenience. Unlike full size loops the tuning one mag loop will have considerably more affect on the resonance of the other loop. In that case it would probably be advisable to orient them in a position that has the least inductive interaction ... probably at right angles to each other ... as I think someone else has suggested.

Jim,

VE3CI

Hi Jim
I had a hunch that it would not be a s simple as hang one one inside the other, :)
Getting the 80 mtr mag loop within 15@ of the tower the VHF arrays are on detuned it, surprisingly
it resonated higher in frequency, I would have expected lower.
I'll gather the bits I need and play..

thanks

7269. Magnetic AM Loop Antenna Construction

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-11 22:09:45 UTC
From: Adam E
Topic: 7269 Message: 7269

I need to learn more about magnetic AM loop antenna construction. I have an HD radio receiver that is called the HD-100 Radio-sophy small
portable boombox. I tried the AN-200 Grundig AM Loop Antenna, but it does not cut out background noise on WCBS-AM and other semi-local stations. Most of the stations are not locking in just the digital blue LED flashing. I want to learn more on how to construct a AM loop antenna using magnet wire, variable tuning capacitor, and aluminum foil for shielding. I have already constructed a active antenna with MW tuning using an old radio shack 20-280 active antenna. Help would be appreciated. Thank you.

how about search on AM loop antenna. Lots of hits, homebrew, commercial, shielded, unshielded designs of different sizes. Size can be important but so can how well it looks in a home environment unless your listening position is in the garage. Mounting the antenna outside your home might also be a possibility to further reduce noise levels.

http://members.cox.net/rwagoner/columns/am_antenna.html - is an untuned loop design from Carver Corporation. I haven't tried it but sounds like like a simple construction project. makearadio.com has several designs that focus on the furniture aspects of the antennas. Nice looking. Oh yeah, the loops work, too.

There is a point of diminishing returns as you get larger. For an AM broadcast band (MW) loop it is not worth the effort to make larger than about 3' or 4'.

I am presently using the MTM Scientific AM Loop built from the plans.

http://www.mtmscientific.com/loop.html

A photo is on the page in this link:

http://www.mtmscientific.com/amcust.html

This loop is 12" on a side, 17" diagonal, 15 turns of 22 ga enameled wire ("magnet wire") with 1/8" spacing between turns, and a 10-380 pf tuning capacitor (may be called 9.6-365 pf, or 10-360 pf, etc, by different suppliers, but these are all the same tuning capacitor). In addition, there is a one turn "pickup loop" just inside of the 15 turn main loop. This pickup loop is connected to the two binding posts you see in the photo above.

I can place this loop near my Grundig S350DL, which picks up the signal from the loop with it's internal ferrite bar antenna. I can also hook up the loop to my Icom R75's high impedance terminals or to the AM antenna and ground terminals of any of my AM/FM stereo tuners or receivers with excellent results.

These loops are quite directional.

After Hurricane Gustav when my dipole was still down - it did not blow down, I took it down prior to the storm - I used a loop that I had slapped together quickly similar to the MTM Scientific SW loop.

http://www.mtmscientific.com/swloop.html

This consisted of a simple wood cross made from some scraps of fir molding, about 36" on the diagonal, one turn of 12 ga wire, with a 10-380 tuning capacitor and a small pickup loop. It could tune from just below 80 meters up to about 17 meters.

I made the pickup loop for this SW antenna from a piece of RG-58 coax, making the loop about 12" diameter, and connecting the center conductor of the end to the shield where it was looped back upon itself. I just twisted it together and secured with tape. I used a crimp on PL-259 on the other end to attach to my R75.

Adjust the frequency range by making the one turn larger or smaller.

I could pick up the various hurricane nets and other nets, and hear most of the checkins from around the region... not state... region (LA, TX, MS, AL, AR, OK, etc) with the R75 by just turning the loop a bit to get the direction to the stations calling.

The AM loop goes up to just above the 160 meter band (about 2.1 mhz), and the SW loop I made covered from about 3.4 mhz to 19 mhz. What more do you need?

I've made several loops using the calculator Tim referred to, and that gives pretty good results.

Most of the stations are not locking in just the digital blue LED flashing. I want to learn more on how to construct a AM loop antenna using magnet wire, variable tuning capacitor, and aluminum foil for shielding. I have already constructed a active antenna with MW tuning using an old radio shack 20-280 active antenna. Help would be appreciated. Thank you.

> larger than about 3' or 4'.

I agree 100% but that is not because BIG loops don't work better (meaning increased performance). You are right but the reason for diminishing returns are many, not the least of which is just moving a 2' box loop manually indoors is a pain... much less 3' or 4'. That is the true drawback.... If course the radio is a limitation and as you get larger loops and impedance changes, on and on. I have seen some really larger loops, and at first it was thought they did not work, but after you tune them and experment they do amazing things.

Last there is only so much signal at your location. The fact of life if noise floor (SNR) and so one means that a super big antenna is handicapped the same way a smaller loop is. Getting a bigger loop will not help.... So you are right but it is complicated as well as practical factors that limits the max size that is optimal.

The ultimate would be a phase array of many smaller loops.

Cheers George

I have used a fat ferrite rod from Stormwise.com, and wrapped ~48t of litz wire on it as the main winding, and about 3t for the low Z output. [in this case ~450ohm], to go direct to my R75 input. Tuned with a varicap, around 10-365pF. Nominal inductance of the main winding is around 300uH or so for resonance throughout the AM BCB. Very high Q, works well. Quiet. Can even be coupled to a preamp if nec. for even more gain. Ramsey puts out a fantastic PR-2 amp for around $60 assembled, and this has over 20dB from 1-1000MHz. very low noise figure, ~1.5dB, and over 15dB IP3.

I recently tried a aperiodic loop with the PR2 using wire, in a hexagon, about 1.2m across, terminated on the far end [top of loop] with a 100 ohm non inductive resistor, fed into the amp at 50 ohm using a BNC. Very consistent gain from just below 800kHz to well into the SW region. [only tried 25m band as max so far]. Rigging up a better one today, using 12 guage stranded inside plumbing hose [1/4" stuff] and making into a circle. I can then rotate it to try for directivity, etc.

Try and make it round at about 3 foot, try and find some under ground piping or use some bent PVC channel held at the bottom with a block of wood, or make a double H frame of plywood about 3.5" wide one vertical the other horizontal this will give you 8 sides to put your turns on, also try and tilt it / turns would be 9 with 500pF tuning variable. mike MBR UK.

Darren, this is something that I have wanted to build. Which ferrite rod from Stormwise did you use?

I used the 13.5" unit, I actually got two of those, plus a 5.6" rod, for another project. The 13.5" is very long, but really works well. I wound my litz on the middle of one side for the tuning winding and the coupling [hi-Z to radio] winding. Since the outside of the coil is polyethylene, I used Weldbond, a white glue in thin strips to hold the windings on. This can be considered semi-permanent, since one CAN remove the whole thing by scraping gently with a knife. Left alone, they stay. Once dry, they do not affect the Q of the coil, but keep the windings firm and held. One could probably use hot glue also, but this worked really well, and is almost invisible when dry.

Stormwise suggested a minimum of 10" for the 125u rod for best overall sensitivity and performance. The 13.5" rod is nearly ideal. VERY sharp nulls, VERY directional. I plan to try coupling it to my Ramsey PR-2 preamp to play with getting big signal out of it. I tried awhile back the noise antenna input on my ANC1 phaser [that side has a hi-z input for a "noise" or aux antenna that has variable gain]. using modest gain, this combination easily outdid my TCF antenna [CCrane Twin coil Ferrite] - it had lower noise, and I had access to even more gain, had I wanted it.

The Ramsey PR2 preamp is rated at +23dB for 1-1000+MHz, though one unit I have been playing with is easily good to below 700kHz, and even has decent gain to 500. I estimate the rolloff is around 1 decade/0.3MHz [10dB/300kHz] below 900kHz. That's still around 13dB near 500kHz, plenty to help the unit.

My suggestion is to find the largest enclosure you wish to mount this into, then go one size down. 10.5-15" is plenty to work with.

Darren

7280. Aperiodic antenna experiment: indoor solution?

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-17 19:52:39 UTC
From: Darren Hennig
Topic: 7280 Message: 7280

I recently tried an aperiodic variant to a loop for general SWL/BCB receiving. My initial results have shown my prototype unit to OUTDO both my AOR WL-500 and LA390 in many respects. More on that in a few...

QTH Situation: I currently live in an apartment/condo complex, 15m from the electrical room of the facility, and 25m from the boiler room. While these can be a source of significant QRM [man-made noise for you non-hams!], the biggest issue is general QRM from adjacent suites, esp. light dimmer units and such. I am at ground level, facing South. So, most transpolar signals have to travel through the complex, to get to me. No balcony/deck, so generally no outdoor antenna easily done.

While my indoor loops have done a pretty decent job, the main issue with the WL-500 is that it really falls off below 3MHz and BCB is rather weak. The LA390 overcomes this, being tunable from 150kHz to over 30 MHz, but it requires band-switching, and being a desktop style, can be a bit touch to find an ideal location for minimum noise pickup from the main element. The unit can be "extended" using coax to 5m max, but even so, I find that rarely do I ever get noise below S6-S7 on my R75 in the SW bands. Very tough to dig out all but major broadcasters...

After reading a bit obout aperiodic loops, and having recently aquired some Ramsey PR2 preamplifiers [1-1000+MHz, 23dB Gain, <1.5dB n.f., +18dB compression point] based on the new microwave MMIC units out of Japan [~$US60/ea, preassembled], I decided to try using one with an aperiodic loop element design.

My trial antenna was surprisingly simple: 3m total AWG#18 stranded wire, cut into to elements, with a 100 ohm 1/2W non-inductive resistor bridging the two. The unterminated ends went to a BNC connector, and the input of the amp is a BNC. I hung this on an eyelet hook I was using for my WL-500 element about 1m from the window, and made a "spreader" using a small 0.85m, 3mm thick rod of plastic composite from an old kite I used to have. Two plastic clips hold the spreader to the wires to keep a diamond/square shape. Apex has the 100ohm resistor, lower apex has the AMP and connections.

Not fancy, I admit, but this was to test the concept. Initial tests relative to the LA390 showed nearly equal signals [within 3dB or 1/2 S unit] to 12.2MHz, with noise levels [once the aperiodic loop was oriented in minimum noise position] at least 3-4 S units lower than the LA390 in its best minimum noise/max signal orientation. Some situations showed the AOR LA390 a bit higher in signal, but with MORE noise. Down to 1.4MHz, the two were pretty close, though the AOR's tuning ability did allow some BCB DX to come in stronger, albeit with more corresponding noise too. Could not copy Bulgaria on 5900kHz with the AOR [heard something, but too noisy, same on 9420/Greece]; Aperiodic had these licked with at least S7/8 to S9+10dB on the R75 and solid copy. Even VOR (Russia) on 12030 kHz was much cleaner and stronger with this aperiodic.

Here's what was VERY interesting: around 0500Z, I played with the aperiodic on 80m - the AOR could dig out 1-2 strong amateur stations, and the aperiodic loop easily could pull out in excess of 12, in some cases, with weaker signals copied 'under" stronger ones on the

same frequency!

To date, this experimental antenna is superior in general tough signal handling that anything I have used indoors. and it does not need a tuner! One could be employed on the output, and I may try this, but so far, I do not need one! AIR came in 20+ over S9 on 9425kHz, THE BEST and cleanest signal I have heard from that station ever - using the aperiodic wire loop.

Given the huge disadvantages in location described above, I realize that nothing can solve everything. However, I have yet to couple this unit to my Timewave ANC1, which should clean up some residual issues, and given that in general signal/noise has improved over 20dB from what I have had in general, This will be my main indoor antenna from now on! No tuners/tweakers, etc. just a simple loop to a very good amp.

During rotation tests, this unit indeed has the [apparent] cardioid type null on one side of the loop.

I mention this to all who have similar issues and locational constraints: Given slightly better to much better conditions, an aperiodic loop with this amp should be very quiet, and a solid signal performer for your location, and the cost for everything is less that US$80. Certainly < US$100 with coax and such.

The PR2 is preassembled, but could be made to a remote amp/loop system by removing the guts and running a power-over coax scheme.

For those wanting to try coverting a whip-style untuned active unit into an aperiodic, the way to do this is to attach one end to the antenna side, and the other side to ground. Make sure that your loop is planar and terminated in around 100 ohm at the location oppsite the feed. I will probably try a more robust loop using either copper or brass strap, or thicker tubing. One can increase the low-band performance by lengthening the size of the circumference to favor lower frequencies, just remember that on the high freq. end, keep in mind that as the antenna approaches 1/4 wave it reaches an upper limit for the design. Since this unit can go well over 100MHz, it could be useful as a VHF/UHF system with appropriate element feed.

Good DX!

well, Mr. Hamilton,
I read the description too, and it sounded like a plain old loop to me, not sure what would make it aperiodic, unless there was more than one in an array? A sketch of some sort would be nice, as some of us need to "see" stuff rather than just read about it.
I've gotten to the point now, after many years, that I can read a circuit description, and that's fine, but I don't really "get it" until I look at the schematic.

Hello Pappy

Presumably the 100 ohm resistor makes it an aperiodic/broadband antenna.

Here is one definition that I found

Antenna designed to have constant impedance over a wide range of frequencies
because of the suppression of reflections within the antenna system;
includes terminated wave and rhombic antennas.

Tracey

I did not wish to start a war of wits here! ;-)

While Mike may be having a bad day [St. Paddy's day blues?], thanks for the comments David!

Mike, I'll make this shorter!
Basically, the loop is a terminated variety - one turn in this case - BNC centre connection [can be direct with wire or a very short [<5cm] run of coax off a BNC] to a wire, in my case AWG #18 stranded, insulated. wire is about 1.4m long. Then goes to a 100 ohm 1/4-1/2W non-inductive resistor. other side of resistor to another 1.4m piece of #18 guage wire, to the ground on the BNC connection.

BNC connector direct to Ramsey PR2 amp input. Hang wire loop at apex [where 100 ohm resitor is now] on a nail, off an eyelet, or similar. put a small 0.8m spreader made from plastic rod, thin dowel, or similar at middle of loop sides making a diamond shape. THat's it!

I'll do up a simple drawing or photo later very shortly.

Trick is to keep leads to AMP short, and minimize resistive losses [good solder connections], and make as planar as possible. Loop dimensions are not critical per se - longer loops will favor low bands to about where their circumference approaches 1/4 wave. Loop would be even better if circular, octagonal or hexagonal [more area per circumference]. More ideal elements would be 1/4" copper tube, or even better, 1/16" x 1" strips of brass or copper [aluminum certainly usable too] in lieu of wire.

Darren

Hi,

Years ago there was an antenna product advertised in QST and other Ham periodicals sold as a broadband matching device. I don't recall the name. It was literally a sealed block with a coax input connector and a pair of terminals to which a dipole or loop could be attached .... regardless of length (longer the better). QST published an expose of the device and declared it was, in their terms, a 'fraud' and the block simply contained a 100 or 150 ohm resistor !! However, there had been many testimonials that the device worked vy well .... and it was highly recommended !!!

Putting the event in context ... it would seem the device created a special kind of aperiodic antenna !!! The customers were happy as it represented reasonable SWR on all HF Amateur bands and apparently enough radiation to meet their approval. It could of course serve 2 purposes ... in addition to being an aperiodic antenna ... one had simply to remove the antenna wire and it would become a 100 ohm dummy load hi hi.

Jim

>
> I recently tried an aperiodic variant to a loop for general SWL/BCB receiving. My initial results have shown my prototype unit to OUTDO both my AOR WL-500 and LA390 in many respects. More on that in a few...
>
> QTH Situation: I currently live in an apartment/condo complex, 15m from the electrical room of the facility, and 25m from the boiler room. While these can be a source of significant QRM [man-made noise for you non-hams!], the biggest issue is general QRM from adjacent suites, esp. light dimmer units and such. I am at ground level, facing South. So, most transpolar signals have to travel through the complex, to get to me. No balcony/deck, so generally no outdoor antenna easily done.
>
> While my indoor loops have done a pretty decent job, the main issue with the WL-500 is that it really falls off below 3MHz and BCB is rather weak. The LA390 overcomes this, being tunable from 150kHz to over 30 MHz, but it requires band-switching, and being a desktop style, can be a bit touch to find an ideal location for minimum noise pickup from the main element. The unit can be "extended" using coax to 5m max, but even so, I find that rarely do I ever get noise below S6-S7 on my R75 in the SW bands. Very tough to dig out all but major broadcasters...
>
> After reading a bit obout aperiodic loops, and having recently aquired some Ramsey PR2 preamplifiers [1-1000+MHz, 23dB Gain, <1.5dB n.f., +18dB compression point] based on the new microwave MMIC units out of Japan [~$US60/ea, preassembled], I decided to try using one with an aperiodic loop element design.
>
> My trial antenna was surprisingly simple: 3m total AWG#18 stranded wire, cut into to elements, with a 100 ohm 1/2W non-inductive resistor bridging the two. The unterminated ends went to a BNC connector, and the input of the amp is a BNC. I hung this on an eyelet hook I was using for my WL-500 element about 1m from the window, and made a "spreader" using a small 0.85m, 3mm thick rod of plastic composite from an old kite I used to have. Two plastic clips hold the spreader to the wires to keep a diamond/square shape. Apex has the 100ohm resistor, lower apex has the AMP and connections.
>
> Not fancy, I admit, but this was to test the concept. Initial tests relative to the LA390 showed nearly equal signals [within 3dB or 1/2 S unit] to 12.2MHz, with noise levels [once the aperiodic loop was oriented in minimum noise position] at least 3-4 S units lower than the LA390 in its best minimum noise/max signal orientation. Some situations showed the AOR LA390 a bit higher in signal, but with MORE noise. Down to 1.4MHz, the two were pretty close, though the AOR's tuning ability did allow some BCB DX to come in stronger, albeit with more corresponding noise too. Could not copy Bulgaria on 5900kHz with the AOR [heard something, but too noisy, same on 9420/Greece]; Aperiodic had these licked with at least S7/8 to S9+10dB on the R75 and solid copy. Even VOR (Russia) on 12030 kHz was much cleaner

and stronger with this aperiodic.
>
> Here's what was VERY interesting: around 0500Z, I played with the aperiodic on 80m - the AOR could dig out 1-2 strong amateur stations, and the aperiodic loop easily could pull out in excess of 12, in some cases, with weaker signals copied 'under" stronger ones on the same frequency!
>
> To date, this experimental antenna is superior in general tough signal handling that anything I have used indoors. and it does not need a tuner! One could be employed on the output, and I may try this, but so far, I do not need one! AIR came in 20+ over S9 on 9425kHz, THE BEST and cleanest signal I have heard from that station ever - using the aperiodic wire loop.
>
> Given the huge disadvantages in location described above, I realize that nothing can solve everything. However, I have yet to couple this unit to my Timewave ANC1, which should clean up some residual issues, and given that in general signal/noise has improved over 20dB from what I have had in general, This will be my main indoor antenna from now on! No tuners/tweakers, etc. just a simple loop to a very good amp.
>
> During rotation tests, this unit indeed has the [apparent] cardioid type null on one side of the loop.
>
> I mention this to all who have similar issues and locational constraints: Given slightly better to much better conditions, an aperiodic loop with this amp should be very quiet, and a solid signal performer for your location, and the cost for everything is less that US$80. Certainly < US$100 with coax and such.
>
> The PR2 is preassembled, but could be made to a remote amp/loop system by removing the guts and running a power-over coax scheme.
>
> For those wanting to try coverting a whip-style untuned active unit into an aperiodic, the way to do this is to attach one end to the antenna side, and the other side to ground. Make sure that your loop is planar and terminated in around 100 ohm at the location oppsite the feed. I will probably try a more robust loop using either copper or brass strap, or thicker tubing. One can increase the low-band performance by lengthening the size of the circumference to favor lower frequencies, just remember that on the high freq. end, keep in mind that as the antenna approaches 1/4 wave it reaches an upper limit for the design. Since this unit can go well over 100MHz, it could be useful as a VHF/UHF system with appropriate element feed.

Such an antenna was described in RadCom in November 1982. The antenna was manufactured by C&S Antennas Ltd and was used as part of a broadside array for monitoring purposes...I guess! Copy of the article on request to my direct e-mail: NOT HERE! Thanks.

7298. "base loading" a full wave loop antenna?

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-19 15:00:01 UTC
From: david feldman
Topic: 7298 Message: 7298

I've got two 20M full-wave wire loops up and running.

I'd like to use them on 30 and 17M (in lieu of building more loops); this is due to a severe space limitation in my tiny suburban antenna farm.

The approach I'm considering is to put a small amount of inductance at the feedpoint of the two loop wires where they enter the (4:1 LDG) balun) to reach 30M band, and do the same thing with a small amount of capacitance to reach the 17M band. Relays at the feedpoint (bias-tee before the balun) would be used to select C-, L- or absent loading.

In the past, I've used an online tool to calculate estimated inductance to shorten a loaded quarter-wave vertical and it's worked well.

Short of cut-and-try experimentation or trying to use modeling tool, is there a recommended way to calculate the estimated lumped values to do this?

Thanks,

Dave

Hi Dave. Are these present loops horizontal or vertical ? Why not just erect the largest practical sized loop, add some medium impedance feeder and tune up in the shack. Alternatively, run coaxial cable from the shack to an auto ATU at the feed point of the loop. You will be able to work several bands, including 15-12-10 and 6 metres. Non resonance is not illegal !
The 300 ohm feeder here can be strapped and fed against earth in the shack end for 160 and 80 metres. Have a look at the W4RNL "Cebik" site for further inspiration. His legacy lives on.
Regards, Mike, G4HOL

7301. 2M Loop?

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-19 20:03:12 UTC
From: Bill McGraw
Topic: 7301 Message: 7301

In the photos by Roberts 50000 dated 4/1/06 shows a 2M Loop and I wonder if this is legit or an April Fool's joke? I would think possible, yes, but would not work at less than a mile.

This puzzles me.

If I understood your description correctly, you hung it so the loop is vertical. It's also symmetrical ... except that the connection is not balanced, one side is shield ("grounded"). Except for that one fact, I don't see how the loop could have an omni-directional pattern in the horizontal plane.

If it is because of that ground connection, then it will be highly dependent on your external connections and stray coupling to earth, through the preamp's power supply and the receiver. Highly variable. In other words, the feedline, preamp, power supply, receiver, etc. are receiving significant signal too and are part of the antenna!

It looks like you did some research on this, or based it on something you read. Yes?

Regards,
Andy

Yes, Andy.

The feed line and radio are NOT part of the antenna. Cannot be since the output of the amp goes to the radio, the amp itself is attached to the loop.

The power supply cable is through a full-wave bridge and voltage regulator [my supply is 12VAC] Note the ramsey schematic included in the photo section.

You are assuming common mode reception here. My run of RG174 coax for the trial test is only 8'. This is also indoors, and it is very unlikely.

However, ANY coax going to the amp off the loop would contribute and ruin the performance somewhat since the unbalanced nature of this terminated loop would force common mode current in the line prior the amp. My amp is connected directly at the loop feed.

Yes, it IS vertical. One side is at the ground side, one at the centre, and both connect via the 100-ohm resistor termiation at the apex of this loop.

THe omni pattern is part of the loop's performance, the other is a standard loop figure 8. Most terminated loops like this inherently have a combination pattern, which arises from two closely spaced IN phase monopoles [which the legs of the loop technically are], and the loop itself which acts like a loop, albeit with a lumped impedance.

The impedance at the termination is to provide some isolation of the sides of the loop and to reduce impedance swings which would occur in a "normal" loop. maybe Chris Trask can comment and provide better info that I?

All I can say is that this amplified aperiodic loop is quiet, has good signal gain, better overall indoor performance than my tuned commercial loops, broad bandwidth, and it WORKS.

Andy:

Yes, I DID a LOT of reading, experimentation, and understanding this - while no radio engineer or expert per se, I have 30+ years in the hobby, and 15 as an advanced amateur - no I am no know-it-all, but I think I have a bit of understanding here...

You're waaaayyy overanalyzing the antenna, IMO. First off, the loop has a varying response dependant on orientation. If my system was susceptable to common mode issues, this would undoubtedly swamp the antenna system and reduce or eliminate altogether the loop's signal response.

Further, using the SAME cable to the radio, with my tuned commercial loops, I get significantly more noise. if the cable to the radio were the cause of signal pickup, it would behave similarly in all cases.

Disconnecting the amp/loop yields very poor signal, and more noise if left unterminated. Unplugging the amp as connected results in NO signal.

Unhooking one end of the loop deliberately, it also performs far worse than as described when setup as a terminated wire loop - almost no signal, some with the centre connected, none with the ground only.

I think that sometimes, folks overanalyze to understand something and they just create a quandry. For about $2 or less in wire, and a 100-ohm resistor, you can try this for yourself, assuming a 50-ohm unbalanced decent amp is available.

If not, try [if your rig has an internal preamp] connecting the loop directly to a radio, and run the preamp(s). It's harder to rotate for best S/N, but will prove the design.

I am not insulted, and understand that this type of antenna is a bit hard to get one's head around - believe me - I recall reading the 1994 ARRL book on aperiodic receiving loops and it had almost nothing to say other than a simple diagram and 1/2 paragraph with no details.

I have been semi-interested in these since. However, I have experimented with many recieve antennas, and while others work well, this one REALLY does fantastic given a sub-floor, noisy and weak signal environment to begin with - I suspect if I can set up a comparable unit outdoors, it'll be fantastic! I finally, since having this new Ramsey PR2 amp, a decent 50-ohm amp with enough gain, decent noise figure, and low IMD enough to finally give this thing a go, and it worked - even better than I had initially hoped.

The initial tests I did was with a 4m hexagonal loop done on one wall of the room. It was very good, but not as low noise, due to the location - not being able to null [the noise null is rather sharp with this loop I am using now] as well, due to the fixed nature of this first trial loop. AM BCB was stronger with the larger loop - expected.

I posted this information mainly to assist those poor souls such as myself, who have been experimenting with antennas to minimize noise, maximize signal, in a small, restricted space.

Good DX,

Darren

That is an incorrect statement. The preamp is attached not only to the loop, but also to its power source, and to its output cable to your receiver. All these wires also pick up signal, which is electrically connected to one side of the loop, and they combine with the signal picked up by the loop.

Put another way, the loop is connected through a wire to your receiver, and through a diode to a wire to the preamp's power supply, and from the receiver to whatever else it is connected to, including its power source. All these things are part of your antenna, whether you want them to be or not.

Consider a loop with no connections to it, except some tiny battery powered receiver at its feedpoint with nothing else connected to it. Now touch the loop. You have now altered the antenna, and it will receive differently, because signals being received by your body, are connected to the loop too. You have become part of the antenna. And it's the same whether you touch the physical loop itself, or a wire connected to the loop.

I think you need to either balance the loop, or isolate it (xfmr), to eliminate these effects.

> You are assuming common mode reception here.

Effectively yes.

> My run of RG174 coax for the trial test is only 8'. This is also indoors,
> and it is very unlikely.

It makes no difference how long it is. The fact is that you made a connection to something else. It could be a 1" wire making that connection.

Eight feet compared to a ~three foot diameter loop, and a lossy one at that, is not insignificant.

Indoors or out, makes little difference. If anything, indoors is worse because there are so many nearby things to couple to.

> THe omni pattern is part of the loop's performance, the other is a

Eh??

> Most terminated loops like this inherently have a combination pattern,
> which arises from two closely spaced IN phase monopoles [which the legs of

> albeit with a lumped impedance.

Fine, I believe you that a terminated loop might have a uni-directional pattern, in the direction toward or away from the terminating resistor. (Similar to how rhombic and beverage antennas do.)

But hung vertically like this, the loop itself is symmetrical in both horizontal axes, so I can see nothing that would cause it to have a cardioid pattern.

Except that you've unbalanced the loop by adding a bunch of wires to one side of it. So if you in fact measure some uni-directionality, I think it is probably because of those connections to non-loop antenna elements. If the loop were isolated from them, it wouldn't be cardioid in the horizontal plane.

> All I can say is that this amplified aperiodic loop is quiet, has good
> signal gain, better overall indoor performance than my tuned commercial
> loops, broad bandwidth, and it WORKS.

And in the end, that is what matters! Enjoy it!

Regards,
Andy

Andy:

As much as it's fun debating this issue, there's no signifcant common mode operation with this unit. If there were, I'd see some signal coming off the unit unpowered, and I am not. Not at HF.

It IS highly probable that SOME and it's tiny... signal may be contributing from the coax, but given the loop's location and the fact that then you're implying that ANY unbalanced antenna is forcing common mode issues in all circumstances, which is an overgeneralization. I added a choke balun [current choke] to the output, and did saem with the power cord - no change in performance that I can tell.

You're right! So long as it does the trick! I am going to build an outdoor version powering the unit via coax from the shack in the near future. I suspect this will perform even better. Care will be done to avoid common mode issues that I KNOW may occur on longer outdoor runs of coax.

Andy,

time to refresh your antenna theory, my man!

Let's just say that you are wrong on all counts. Sorry, tried to make this act similar in common mode in many ways and it is not. So let's leave it at that. [I love it when folks who do not understand things try to posture and make idiots out of themselves...]

A balun won't be any good for this loop - it is deliberately terminated and unbalanced by design. and anyway, so what? according to you, anything connected to this thing, balanced or no, is an antenna. Give it up please. I am tired of explaining to folks who are posturing as know-it-alls. [and I am not saying I am, but enough RF elmer thinking already!]

Because YOU cannot see it having a cardioid pattern, it is not my fault, sir. Take a closely spaced dual monopole in phase - this is approx [though close in the far field] an omni pattern. yes? Good. now add this to a standard loop behavior, also present somewhat since the terminating resistor partially isolates the legs, thus, my understanding is that it can still have some out of phase behavior to it, and when added to the monopole behavior, you get a cardioid. Toroid plus sphere [in 3D] is a fat cardioid like pattern. Get ye back to physics class! ;-)

It is NOT a lossy loop either. it is DELIBERATELY made to run as a terminated, small loop to yield more uniform Z over a large raneg in NON-resonant fashion. when fed into a good, broadband amp - it acts as you're seeing. Do NOT let the simplicity of the test loop fool you - it may seem counter intuitive somewhat, but I would not have wasted all this time explaining this bloddy thing to everyone here if I thought it was simply a small loop adding to some coax as a makeshift wannabe homebrew nothing antenna! I have better things to do with my time, and I suppose many here do too. If you do not believe me, make one and see.

Sorry, but your posts remind me of some things I see on other hobby related sites even though I may be misreading your intentions. asking is better than telling in this case, cause you do NOT know what you're saying - you THINK so, because that's what you know. I've been trying to analyze this thing coming on 10 years before making this simple one, and I have done everything possible to test, isolate, and prevent the things you have said. the thing works the same. So, I left it as is.

I am done now, Try one if it suits you, don't if you don't - is it perfect? no, just a potentially good solution for some SWLers in tough signal areas.

Darren

7309. Wanted vacuum relay/switch

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-21 16:02:48 UTC
From: richard
Topic: 7309 Message: 7309

Hi all
I'm looking for a low cost vacuum relay / switch I only need 1 pole normally open.
Not more than 3" (75 mm) long, preferably in the EU. Out side of the EU is OK if below Customs
duty level.
I've been googling for a few hours, I've seen some really silly prices.
Its needed for switching in a capacitor on my 4 mtr dia mag loop I use on 80 mtrs so I can use it on
160 mtrs as well.
I did think of trying one of the larger reed switches , but I think the capacitance maybe too high
when open.
I'd like to be able to keep this antenna capable of handling 400 W if possible, so when the switch
is open somewhere in the region of 5 KV across it.
TIA

Hi Richard,

I have stock of DowKey Microwave 401-2308 Relays, HF 500W - with SMA connectors which are new old stock taken from redundant spares. If any use to you, email me off list and I will ask my Son to mail you one, providing he can cope with my stock system, I am in India. If you wish I can email pdf data.

Regards to all

You don't need to know a lot. A full size loop for 27mhz is 37.22 ft in circumference .... 9.3 ft per side if you form it into a square. Cut the wire in the middle of the bottom side and connect the end of standard coax cable. Connect the other end of the coax cable to your CB radio and it will work like gang busters. All you need to do is devise a method of holding the wire in a more or less square configuration and mount it up as high as you can get it .... there, done.

Jim

Hi
looking at your e-mail address, do you intend to transmit into it and how much power ?
and why experiment with an antenna with an efficiency less than that you can readily purchase at CB shops ect.

Inductance (uH) 1.704
Capacitance (pF) 20.4
XL = XC (ohms) 289.1
Distributed C (pF) 6.7
Tuning capacitance (pF) 13.7
Main loop diameter (m) 0.796
Feeding loop diameter (m) 0.159
Radiation resistance (ohms) 0.514
Loss resistance (ohms) 0.038
Parallel resistance (kohms) 76
Efficiency (%) 93.0
Compared to ideal loop (dB) -0.31
Loaded Q 261
Bandwidth -3dB (kHz) 103.3
Capcitor rms voltage (V) 2749

Thats with 2.5 mtrs of 28 mm Copper water pipe bent into a circle with a 20 pF capacitor connected
across the open end. Fed with another smaller loop of say 2.5 mm wire at the opposite end to the
capacitor.
And after all that effort of bending the 3/4 " copper pipe you will have an antenna with less gain
than a 1/2 wave dipole.
45 degree 28mm solder bends are available and then you can make it octagonal.

have fun

Todd Roberts is having problems with his email not showing up on the list, so I'm forwarding his reply:

Hi Bill,
Yes the 2M loop works very well. I took some pictures of it to show others how easy it is to build one. I built mine in an afternoon. I compared it with a friend using a homemade hand-held 3-element quad beam out in the yard and the loop worked better with lower noise than the beam did on a distant repeater, both antennas held about 5 feet above ground level. The beam might work better higher up in the air but at 5 feet above ground the loop worked much better. It would make an excellent antenna for a handie talkie.

To use it with a repeater I tuned the loop for best SWR at the
transmit frequency and it still works fine on receive although the SWR is not as low on the receive frequency. The loop is a fairly narrow band antenna on transmit. You will need to retune it when going from one repeater to another. It is also very directional with sharp nulls off to the side.

The loop uses a gimmick capacitor at the top gap of the loop for tuning and it did not get warm at 25 watts. I used an MFJ-259B to tune the loop at the transmit frequency. I still have the loop and it still works fine. The loop is an excellent portable transmit antenna for 2 meters when it is built and tuned properly.

7317. Re: Aperiodic antenna Drawing

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-23 07:45:16 UTC
From: xtemporize
Topic: 7286 Message: 7317

I bought one of those "fold-up laundry baskets" for the spring wire thinking to use it for loop material, in the way that the Sony loop is made. I have not tried yet to see how solderable it is.
I also found an old spool of "fish tape" used in telecom work for inserting in wire conduits, but I don't think I will use it after all: while it's heavier and will support a larger loop than the basket's spring wire, the "fish tape" wire is, I think, dangerous if say, some child struck it with a ball and the thing came apart and lashed out.
Aperiodic loops, meaning non-resonant, of course: has anyone bought the Ramsey loop kit? I wonder how many turns Ramsey uses on their ferrite stick frame. What kind of amplifier? If anyone has bought this kit, I offer to buy a copy of the manual from you, for a price worth your while. Ramsey does not sell any manuals with schematic information intact. (The only exception, a book collection of Ramsey project schematics, published a few years ago.)
Say also- i scrounged up some dozens of feet of 2 conductor twisted pair shielded wire, used in telephony work at T1 transmission rate. I am thinking of trying it as "twinax" for completely shielded transmission line in a long run thru noisey area. No, I would NOT use it for transmtting! Any comment?
Thanks- Hue Miller / Newport, Oregon

Hi Chris
yes that sorta size is ideal for camping /portable operation. If you use one of the pop up tents
that are now available and very popular with the people that go to music festivals, you could take
817 ,pop up tent which flat pack down to about 1 mtr diameter. the loop could be packed in the same
package as the tent.
You could be set up portable in minutes, hang the loop on the nearest bush or tree.

Since you like to experiment, learn the theory of antennas especially the formular for a dipole and the current and voltage distribution.
Now turn that to practice by making your first wire dipole.
You shall need an swr meter, or better still an antenna analyser.
There's stacks of information on the net and I am sure you will enjoy it once you start experimenting.

From: sarmento2k
Topic: 7321 Message: 7321

Hi

Just published an article about an air core loop antenna for MW, with photos of the final product.

After some research I have completed this loop antenna with good practical results.

The article is written in English, not Google translation.

http://www.sarmento.eng.br

This is the first article of a series of different loops I have assembled in order to test different concepts of this kind of antennas, next one, will be about portable ferrite loops for MW, let me say, with not so common dimensions. But it worked very fine too.

:-)

Comments are much appreciated .

Regards,

Sarmento Campos - Rio de Janeiro - Brasil

Hue:

The Ramsey "signal magent", I believe you are referring too, is an amplified tuned ferrite loop antenna and uses some form of RF amp using active [transistor] components. I have the kit manual I downloaded off their site, but it only shows positioning of components and no schematic per se. It appears, from what I gather looking at this, to be a standard type of active antenna system using a ferrite loop tuned with a variable to achieve reception. Nothing overly fancy, but it is an interesting approach. Upper f is 15 MHz, so if you listen to the 19m, 16m, and 13m SW bands during solar maxima, you'll be out of luck without a mod of some kind...

For less money, the PR2 can be had, and this is the amp I used for my Aperiodic loop. It's simple, and easy to setup. If this is an indoor application, even better, as the connections can be kept shorter, and the location can be optimized for your best S/N. Your Twinax cable - is it 25 or 90 ohm? any idea of the impedance? You can possibly hook it out from a loop to your radio. I am not sure. I personally like RG174 for indoor work, as it is not as lossy as specs suggest at 10MHz and below, especially. It is not as well shielded as RG8 or Belden cables, but for short runs works fine. You can also clamp some RF ferrite to the cable to reduce/eliminate common-mode noise too.

The loop can be virtually anything from wire to rod/tubing. My next loop, after speaking with Steve here offline, is going to be a copper tube version around 90cm dia. I am going to try it in a circle. If this works even better than my wire loop, which I expect it should slightly, then I'll work on an outdoor version that can be mounted several meters away from my shack to minimize noise issues. I still get SOME noise, esp. when my immediate neighbour in our complex runs a drill or blender, but the levels, due ot the more unidirectional characteristics of this loop, can be nulled out better than using my bi-directional amplified tuned commercial loops in general. Noise levels seem to be at least 15-20dB on average below my other indoor options. I am also getting much better transpolar DX off backs of beams to the ME and African services of DW, RSI, etc. Sweden came in on 9360kHz at over S9 - this is Horby transmitting to Africa/ME - I'm getting their "backside" over the pole. One of my main lobes off this unit seems to be around 030°T, just about ideal for ME and polar DX from Asia, and Europe. Seeing this alot in the mornings, something never able to do as routinely indoors using my AOR loops.

Being able to use this untuned is really nice, as it allows me to "band hop" around to catch new DX or just "twiddle" my tuning knob on the R75 to find something new or coming in better than average.

If you get an aperiodic running, please let us know how you make out! These are very easy to make [loop-wise], and are fun projects!

Good DX,

Darren

Im looking into dipoles now as suggested,current & voltage is confusing as i thought they both flowed inside the wire not above it.

I have a swr meter but not a analyser.

I LIKE the idea of the wheel rim loop antenna cause we get around a lot and it would be priceless for portable.

Cheers Rob

When you transmit through an antenna,what actually travels through space to the other station,voltage or current ? And how does it leave the antenna wire,what pushes it away out into space?
Cheers Rob

Hi
Google OHMS LAW you should realise what the answer is very quickly, that's one you need to learn and
know parrot fashion.
If you are going to spend some money buy either the ARRL handbook, published each year or the RSGB
handbook,
I'm sure there is an Australian version as well. Read the sections on theory, then move on to
antennas and propagation.
I know said you dont want learn parrot fashion as new Hams do, but I suggest you find your nearest
club and get the info on what foundation courses there are for entry level in Aus.
You have to learn some theory, then you will understand what you are being advised and how to
implement it.
If you dont want to contact your nearest club, find out what the entry levels are , get the syllabus
start learning then take what ever entry exams there are.
In the UK the foundation exam is handled by Amateur clubs and is incredibly easy to pass, you then
have access to most of the Ham bands with low power.
The same system will probably operate where you or something very similar.
good luck

Hello Ozzy_1kw and others,

For a small loop antenna you could try this (non-magnetic) loop out of coax.

- http://www.antennex.com/hws/ws0201/nonmag.htm

I made this morning one of these myself to use for SWL out of about 2 meters of coax (that's all what I had laying around right now) and used it for an SWL-antenna with a MLB (RF systems) instead of a 7:1 autotransformer (figure 5). I taped it on the window (my wife is not at home now so... it's gone before she comes at home) It's a unbelieveble antenna. I normally used a magloop but now I don't know. I experiment some more with it to find out.

I listen now to HFDL with it at 11 and 17 mhz and I can see aeroplanes all over Europe (I live in The Netherlands) with a minimum of noise.

With the magloop (about 80 cm in diameter) I normaly can see aeroplanes 4.000 km west, east and south of my QTH. North is a bit of a problem. That's no more than about 2.000 km.
Let's see what the Grey Line brings.

Btw: that magloop is made of a bicyclerim.

7328. T2FD as a transmitting antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-25 20:10:28 UTC
From: Jim Dunstan
Topic: 7311 Message: 7328

The tilted T2FD has been described as the forgotten antenna. It has characteristics of a dipole as well as a loop. It is terminated with a non-inductive resistor opposite the feed point. It is more compact in length than a dipole and professes to be very quiet on receive and broadband , at least a 5:1 frequency ratio. From what I have read it's present use is limited to a broadband quiet SW receiving antenna .... although I understand the US Navy conducted long term HF communications trials and concluded it was more effective than individual wire antennas for HF frequencies in the HF spectrum (a myth ??). If the trial is correct then the antenna must have some sort of gain .... since there would be a starting loss due to the termination.

It sounds like an ideal Amateur radio antenna ... yet I have no experience with it ... nor do I know anyone who has used one. I notice ICOM sells an all band antenna that appears to be a T2FD ... the AH-710 .... again no info on it not even in Eham reviews.

Anyone know anything about this antenna ?

It's a loop that makes up for its lack of circumference with a resistor. To me, it is likely to be a good choice for anyone short of space. Otherwise, use more wire and don't turn transmitter power into heat losses. Copper beats carbon hands down.

What has been forgotten is the noise control benefits of using a relatively low resistive termination. I'm using a T2FD, full size on 5Mhz, mounted inverted "V" style to recieve WWV (all frequencies) for asteriod occultation observations. Tried more than a dozen different antennas to solve the noise problem, T2FD worked much better than all. Doesn't fade out like physically small antennas sometimes do and it just doesn't pick up ever more noise like other full sized antennas. Even works better than the built in ferrite on AM bcb.

Terminated antennas are not necessarily lossy - look at terminated beverages! Does one dump a whole pile of wattage into the resisting termination? No, not really. Otherwise, they would not be used.

The K9AYs I've heard can be run as transmitting loops as well, and I recall vaguely an article using a 900 ohm terminated loop [10' dia.] for TX/RX on 160m not too long ago...

The terminations are to control the impedance to a degree, and regulate the current on the legs of the antenna. since an ideal termination is non-inductive/capacitive, it acts as a pure [or close to pure] lumped impedance to work WITHIN the antenna system, not as a dummy load.

Considering the simplicity of the T2FD in many ways, why not try one out? The only big question is how much RF does go into the resistor, and that will affect choice of wattage.

Folks have to STOP considering resistive elements in an atenna system as a pure dummy load only, and as a part of the whole!

Greetings, Paul!

As I understand it so far, terminated antennae also operate in a blend of transmission line modes as well as bonafide loops. Thus, standard RF analysis need consider the TL modes of operation.

No expert, here, but learning! ;-)

73 and good DX!

Hi Darren,

Many years ago when I was a young fellow ... I worked in an Arctic research station and we had a large terminated rhombic antenna pointed more or less south (where else could it point hi hi) From time to time I would bring a small QRP rig (made from tubes ... e.g. before transistors!) into the station and would work a fellow in a research station in the Antarctic with my 2 watts.

the official commercial use of the antenna was for pulsed transmissions from 2 to 30 mhz. for the purpose of sounding the ionosphere. To this day I have never experienced any other antenna as effective .... even though there no doubt would be some loss in the termination resistor. It sticks in my mind that the termination resistor in the Rhombic was in the 600 ohm range .... which would seem about right given the antenna was fed with 600 ohm parallel feed line.

I agree .... It is not accurate to say, "copper beats carbon every time" in antenna construction .... hi hi

First, my use is SWLing - receive-only. I used a homebrew TTFD for several years - and compared it with my 145 ft lw matched via a pi-network to my various receivers, which was my standard over the years. Also available was an Alpha Delta Sloper. It and the TTFD were fed by RG-8X, the latter matched via a 9:1 BALUN and terminated with a 450 Ohm carbon composition resistance (Four 1.8 kOhm 1 W resistors in parallel.). The Sloper picked up nearl as much noise as the lw, just not as much signal - but no tuner tweaking was needed. The TTFD was the quietest - and didn't seem to have the severe fades the lw had - or noise pickup and rapid signal drop-off the sloper had. No tuner tweaking, either.

That tuner tweaking changed - I couldn't stand it - I refed it with 450 Ohm ladder line - and built a balanced tuner/matcher for the antenna, locating it at the window where the line came in. Too much trouble - the care of a balanced high impedance transmission line is difficult to contend with when you've become accustomed to coax. The time frame was too long, but it sure seemed that the balanced line fed had the good wide frequency range, low noise, but stronger signals than the coax fed version - could have been my 9: BALUN. Sadly, the feedline ended up in a pile of leaves I was muching. My antennas have been down for years.

RF Systems sells a receive-only TTFD that is 45 ft long and fed with 50 Ohm coax ~$400 at Universal. The low noise reception, combined with wide bandwidth, are alluring. At worst, the termination resistance absorbs half your signal - received or transmitted. Not that big a deal for a hands-free wide band antenna - with both vertical and horizontal E-wave components. Size the termination, from 360-500 Ohms dependent on conductor size/spacing, to dissipate at least 50% of your transmitter key down RMS RF output power for CW/SSB - higher for 100% duty cycle, like RTTY. A good 9:1 to 11:1 BALUN, with proper power handling capability, is required - or 450 Ohm ladder line and a good balanced tuner. Go coax!

Last fall I came into posession of the Barker and Williamson T2FD from a SK estate. I found it to be a good, quiet antenna on Rx. For some reason I never keyed up into it beyond taking swr measurement. I did, however, search online and found that L.B. Cebik W4RNL/SK did some extensive testing on it. It is a so-so radiator, less output than a dipole. Its main advantage is in the fact that it's very broadband, making it popular with ALE fans, but there are other antennas that can give good Tx on most of the ham bands. But where other antennas usually require an ATU, the T2FD does not, and with ALE you want fast switching between bands and most automatic ATU's are too slow for that use. As far as Rx goes though, I've had up an 80m OCF dipole, a G5RV and a 135' doublet in the same location. The T2FD has much lower noise than all of those. After I move to a new QTH I may have it up as a dedicated Rx antenna.

This antenna has been modeled a number of times. Its main virtues are size and the ability to transmit on any hf frequency. Main con is it's not very efficient. Not really a problem if you have watts to waste.

If I remember right, the efficiency is below 50%.

Yes, very low efficiency, so low we made no contacts with this antenna last Field Day. Nor did we hear anyone. A waste of wire.

But it had great SWR readings!

I use a 132 ft T2FD as my primary receiving antenna. I also have
several dipoles, one dedicated to each band of interest. The signal
levels on the T2FD are lower than the dipoles (as expected) but the
signal to noise ratio is higher. As a result, I pretty much just use
the T2FD for receiving, it is that much better.

Efficiency of a GOOD design on a T2FD is at best 80-85% with only 15% going to the termination. The 50% figure has been bandied about in ham circles for years, and is somewhat due to the original tester designing the unit wiht minimum SWR in mind only.

excellent Darren !!!, I had kinda thought the answer may lay in this direction

BTW I now immediately determine the typical efficiency is about sqrt(50*85)= 65%
(a engineering prediction method taught to me by Prof Michel Poloujadoff of U of Paris that is typically leading to a good estimate (of whatever))
LOW= 50%
HIGH = 85%
Michel's general formula is the geometric mean = sqrt(LOW*HIGH)

65% now being the likely working efficiency for any reasonable implementation of this design

best wishes

People use short verticals that are <50% efficient too, if I recall. So, the T2FD is not so bad a tradeoff in general, even if less than 80%.

Darren!

I'm a total newbie! I tried this aperiodic loop without the preamp...but I don't get enough signal into my portable Sony 7600GR. Near windows, it's pretty much like using the whip. I'm afraid if I get the preamp, it might overload a little portable like this...since I believe the portables are much more sensitive than the table-top rigs. I recall that preamp gave a gain of 26 dB or so, but there's no gain control knob! What do you think will happen in my situation?

Thanks,
Robert

7347. Balun for LF magloop

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-28 18:13:53 UTC
From: Daniele
Topic: 7347 Message: 7347

Hi all,
I'm new to the LF and just starting to play with an homebrew tuned magloop and my small portable (Tecsun PL-600).
I managed to enable (by means of the soldering iron :-)) the external antenna jack also for MF and LF on PL-600 (normally it only works in HF). Now I can connect the pick-up turn of my magloop directly to the radio but I know it would be better to try to keep it balanced by means of a balun. Here my problem: magloop simulation (with rjeloop3.exe) tells the antenna has an impedance of between 500 and 2500 ohms (on the frequencies it covers, from 280KHz up to 1000KHz). On the other hand, I don't think the receiver have a 50ohm input. In fact, it is designed typically for HF random wires and has a JFET input buffer stage that should ensure an high impedance. Given these conditions, does it still make sense to build a balun? If yes, how could it be designed in terms of number of turns (primary side and secondary side), etc.?
Many thanks for any feedback.

Cebik, W4RNL(sk), modeled this antenna in two different articles.

Modeling the T2FD, and
Notes on the Terminated Wide-Band "Folded Dipole"

These articles are available at

http://www.cebik.com

for free by just registering. Every antenna has a good use, depending on the circumstances. Don't try and reinvent the wheel, though. Do your research to avoid unnecessary expense and wasted time and effort.

In the case of the T2FD, the design has been around a long time. The first chart in the second article "Notes on the ..." shows there is a difference of at least 3db, to the more often 6db, between it and the reference antenna... same length doublet, open wire transmission lines, and antenna tuner. So what does that tell me?

100 watts in with a 3db loss = 50 watts
100 watts in with a 6db loss = 25 watts

If I don't want to use an antenna tuner and open wire line, or can't, then those losses must be acceptable.

If you have 2 antennas with the same S/N ratio, but different
gain, it is fairly easy to get fooled into thinking the
one with less gain "sounds better," is "quieter" or has better
S/N. What you need to do is put an attenuator on the higher
gain antenna to lower its gain down to the level of the other
antenna. After doing this, the perceived difference will often
disappear. The reason for this phenomenon has to do with the
AGC characteristics of receivers. Anyway, this is why I don't
put a whole lot of stock in anecdotal reports.

Any balanced loop has a low noise performance compared with other systems as the positve going noise peaks on one side are cancelled by the negative going noise peaks on the other (at any instant). Putting a resistor half way round can't change that property.

What kind of noise? That's what makes the difference. Resistive termination (T2FD) works better than anything else when the noise is off frequency (front end overload), and that's more of a problem than many realize. Wire length and desired frequency determine impedance and matching a resistive termination to that impedance will cause greater signal loss to off frequency noise than than desired frequency signal.

Doesn't matter how efficient an antenna may or may not be. You've got to get the off frequency noise low enough for the tuner to reject, without decreasing the desired signal too much. You can do that with a big antenna that has resistive termination.

Physically small antennas are fine for transmitting and while they may cut down receive noise they also cut down desired signal received. More metal in the air equals more desired signal received. Regardless of what all the books say; transmit and receive are not reciprocal in practice. It may be hard to recognize that unless you've tried some backyard radio astronomy because ionospheric variations can easily overwhelm any performance differences between the biggest and smallest antennas used for terrestrial work.

Doug Kniffen

The only thing not fully investigated by Cebik is the effect of Resistor and he focused on optimizing SWR only. There may be a range of R's that may trade off amount of power going to load.

FYI for all, remember that a short vertical is <50% efficient, so this is not a totally unfounded tradeoff, given the bandwidth and simplicity. I have seen other reports stating a GOOD T2FD with slightly different layout is closer to 85% efficient in it's best band. I need to see if I can find this again...

In my previous mails I sent you a link for a spreadsheet program from a Finnish amateur,for calculating the loop sizes, that's if your using a mag loop , and not a halfwave loop,
On small loop you may be better off delta with a delta match,
just google mag loop delta match , (good for both types of loop)
and it that all fails start with about 250 mm and trim for best return loss.

The coupling loop is in general between 1/5-1/4 the diameter of the main loop. 1/5, or 20%, should be ideal.

TY Darren, i know where to start now.

Richard i didnt receive a link is it possible i could trouble you to resend it please?

Although im only cb i absolutely love how a bit of wire can pull signals out of the air.

Its a fascination that ive got to learn how and why. Low power antennas dont worry me cause im learning how they work.

My friends have yagis etc and i can get on air with a 28" loop LOL.

Cheers and TY everyone for the help.

Cheers Rob

7359. RE: Hello Chris

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-31 09:16:28 UTC
From: Chris Harris
Topic: 7359 Message: 7359

Hi Rob

Think of the capacitor and the loop (inductor) as being in series not parallel. They exchange energy. The cap discharges into the loop and the inductance keeps the current flowing after the cap has discharged as the magnetic field generated by the current in the loop collapses. Repeat in the opposite direction.
Some of the collapsing magnetic field generates an electric field in free space. When that electric field collapses it generates a new magnetic field in free space etc each way at 26,500,000 time a second. (on the NZ CB calling frequency anyway)
That is the magic. Those free space fields are your radio wave and propagating away from your loop at the speed of light.
As a ham you get to play with this magic.

I never calculate the size of the feeder loop other than to make it about quarter the size of the main loop and then shrink it until I can match to the radio without an antenna tuner.

What you are talking about below with the 6" wire connected to the loop and feed line is a gamma match. I've never liked them because they upset the balance and require an additional capacitor to make them work properly.

I'll send this to the group as someone might have something useful to say about gamma matches to dispel my prejudice.

Cheers, Chris zl3cjh

Subject: Re: Hello Chris

Hi Chris,
Firstly TY for responding. I understand from doing online studies that the wheel ,split ,in parrallel with the capacitor makes a tuned circuit and i appreciate its very low power transmit cause of the capacitor spacing that breaks down .

But what i dont understand is how do you calculate the small loop of feedline opposite the capacitor or bottom of loop?

From what ive seen the small loop is very small.some ive seen have a wire from the coax that grounds to the rim 6" or so around. This is where im baffled.Does the small loop electrically contact the loop or is

it inductively coupled?

I LOVE Radio and im going to become a ham shortly,but lots of new hams here just get copies to the exam questions and learn them parrott fashion,whereas id like to actually know some of it from study and actual hands on.

cheers and TY Rob

Subject: RE: Hello Chris

Hi Robby, it was just a mag loop with a one fifth circumference pickup loop of 2mm copper wire hooked up to the coax feeder and a split rotor variable cap on the cut in the wheel.

Magloop4.exe:

S. Shape of loop ... CIRCLE W. Watts RF power input
4.00
P. Perimeter, metres 2.500 H. Height, metres .....
2.00
C. Conductor dia, mm 30.00 R. Soil type: S,L,A,H,D
F. Frequency, MHz .. 26.450 Low resistance: 30.00
ohm-metres

Electrical length of perimeter 0.221 wavelengths
Diameter of equivalent circle 0.796 metres for same enclosed
area
Loop current opposite tune capacitor 2.77 rms amps
Tuning capacitor setting 17.99 picofarads for resonance
Voltage across tuning capacitor 870 peak RF volts
Inductively coupled ground loss 0.98 percent of Tx output
power
Capacitance coupled ground loss 0.08 .. ..
Loss in loop conductor resistance 5.45 .. ..
Radiating efficiency 93.49 percent

3-dB receiving bandwidth 124.2 kilo-Hz with matched
receiver
Transmitting bandwidth 43.9 kilo-Hz between SWR=2:1
points
Coupling loop diameter 0.169 metres, to match 50 ohms
coax

Loss relative to ideal antenna 0.3 decibels = 0.0 S-units
Path = 800 km: S-meter reading "S"= 6.0 1 hop, darkness, F-layer
8000 km: .. .. "S"= 0.0 3 hops, daylight ..

Vary Freq with keys 1,2 Perim 3,4 Diam 5,6 Height 7,8 Soil ohms
9,0

The tuning was very fiddly and the band was dead, so it didn't get developed much. As for unwanted RF in the house there was plenty because I had it propped up within reach for tuning. Also note the 870 peak RF volts. Certainly makes flies jump off when you PTT :-) When I ran it on higher power the cap arced so strictly QRP. I might reresurect it with a beefed up cap and a servo on the roof now that the bands are opening.

If the oz ham exam is as easy as the NZ one you could do a quick cram and exam and get legal or do you like the outlaw image ;-)

Cheers, Chris

Yea,i think ive got it. They discharge into each other and the radio resupplies the energy to restart the oscillation. The bi product is an electric field that is how the antenna radiates.

I can understand that,but what im having trouble grasping is the small coaxial loop.With that small a loop surely it would see a dead short at the transmitter end. a 6" length of wire cant have too much resistance to balance ohms law??? Or is the feed loop being reinforced by the collapsing magnetic field of the main loop ?

Cheers Rob

Yer tis Rob
use the link for the excel file, download it, make a copy so you have write permissions and run it
is excel. Only change the figures in the left hand column.
ie. where it says 3.5 Mhz , change to 27

http://www.saunalahti.fi/hohtola/ham/magnetic-loop-for-80m/magnetic-loop-for-80m.htm

Have fun

That is a good point Ozzy. I think because of the perceived short circuit many new amateurs are uneasy about loops. Yet they somehow accept a folded dipole more readily. What is a short circuit to direct current can be a good radiator of R.F. Once amateurs can get their heads round that idea, the loop concept opens up (into a group like this!) and the possibilities manifest themselves. Good luck, Mike G4HOL

From: pappy_hiram
Topic: 7359 Message: 7363

think of it in terms of resistance applies to DC circuits, and Impedance applies to AC (or RF) circuits. At resonance, the tiny loop is not a short circuit on the resonant frequency, because it is inductively coupled to the larger loop. DC resistance would be in the milliohms, but the impedance would be much higher. Optimum impedance is around 50-75 ohms. Pruning the length of the loop will eventually find the resonant length for the frequency you are on, and match the output impedance of your transmitter.
The theory is one thing, but until you try it and get it to work, that's when the theory becomes "real."
Have fun with it!
Good luck,

Pappy Hiram

7365. Equipment for sale

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-03-31 17:54:08 UTC
From: neilbellgroups
Topic: 7365 Message: 7365

Now that I have my Ham Radio license I am about to purchase a new all-band Ham Radio Transceiver and they cost $$$$. As a result I will be selling the following:

1. Like new Perseus SDR, with all original items cost new was $1,200

2. Quantum Phaser cost new was $135 + S/H includes power supply

3. Quantum QX Loop 2.0 cost new was $199 + H/S includes power supply

Please make any offers via e-mail and not the group list. These will go on e-bay on April 6 if not sold here. My e-bay rating is 100% positive! e-bay user name is neilbell.

This equipment is in mint condition and performs perfectly. Make me an offer.

Neil Bell

Subject: [loopantennas] Replicating the ALA330s

Hello everyone,

I would like replicate the welbrook ALA330s and have a few questions;

- I'm thinking of using 1/2 inch solid wrought iron to build the 1
metre diameter loop instead coppper or aluminum, any downside to
this? hollow, solid?

- Are there any schematics or photos for the electronics available
online? I found a few posts stating there were pictures posted in
this group but I have not been able to find them.

- Mast material, should I use an non conductive/ferrous antenna mast
to hold the loop? does it matter?

- RG8x coax ok or LMR400 for a 20 foot lead in?

Thank You all for any advice you can provice..

Cheers,
JM

Wrought iron is not a very good conductor, not to mention the rust. But a 10' 4" x 1/2" thick iron loop would be very heavy to support and keep from blowing over. I would assume you already have this material laying around, but aluminum tube is a much better idea. I would use a wood dowel or PVC pipe for a stub mast then whatever below that, even if you don't use a rotator. Works for me. Just about any coax will work especially if there is an amp at the antenna. RG8 or LMR400 is probably overkill. Google Burhans loop amp for a start. Wellbrook has a patent so you probably won't find that.

From: ozzy_1kw
Topic: 7369 Message: 7369

If the tuning is done by the small loop for best swr then for a single band hf cb i can put the exact capacitance required or is the tuning too sharp to cover the entire cb band??

what is the purpose for the variable capacitor ,is it multiband usage ?

TY Rob

PS, i see on youtube the guy that sells loops.his appear to be upside down with the tuning capacitor on the bottom that he tunes with his thumb. is there any issues feeding it from the top and running the coax down the side of the loop ?

Cheers Rob

Rob
If you would bother to use the spreadsheet program of OH7SV, you would see that on a loop diameter
roughly the same as a bike wheel, the 3dB point is about 50 KHz, whats that 4 CB channels ?

Come on you should know that you will never learn anything if you don't try.
Use the spreadsheet that I've now sent you twice.
All you have to do is alter the value in the left hand column, that's frequency , length of the
loop, the conductor diameter(how thick it is) and how much power you are going to put in it.

Results
Inductance (uH) 1.580
Capacitance (pF) 21.2
XL = XC (ohms) 273.0
Distributed C (pF) 5.4
Tuning capacitance (pF) 15.8
Main loop diameter (m) 0.637
Feeding loop diameter (m) 0.127
Radiation resistance (ohms) 0.227
Loss resistance (ohms) 0.067
Parallel resistance (kohms) 127
Efficiency (%) 77.2

Compared to ideal loop (dB) -1.12
Loaded Q 465
Bandwidth -3dB (kHz) 59.2
Capcitor rms voltage (V) 2519

Thats what you get roughly for what you are using.

If you can't get enough decimal places in the left hand column you can change the cell properties,
details of how to do this are in the "help" column in EXCEL and Open office.

If you really want to become a Ham you will have to learn some basic theory
Google is your friend.
If you go to your local club you will probably get given a ARRL or RSGB Handbook where someone has
bought a new one , and doesn't want the old one.
The process of learning is not asking questions to which you have already been given the answer.
but being able to understand what's in front of you.

--
Best wishes

Richard Bown

From: richard
Topic: 7371 Message: 7371

Hi Rob & others

In case you had difficulty finding the information on how to get a Ham licence in Australia,
here are some notes and links.

The amateur Foundation licence. Holders of the Foundation licence can only use a transmitter that
has been manufactured commercially, can only use voice, on either SSB, AM or FM or morse using a
manually operated morse key, and not more than 10 watts output power on SSB, AM, FM or CW. Bands
permitted are the 80, 40, 15 and 10 metre bands as well as the 2 metre band and the band 430 to 450
MHz, subject to necessary bandwidth restriction

http://www.wia.org.au/licences/foundation/about/

http://www.wia.org.au/licences/foundation/foundationmanual/

The exam is very simple, and I suspect there is some practical work to be done, that again is very
easy.
http://www.wia.org.au/licences/foundation/trialexam/

http://www.wia.org.au/licences/foundation/learningorganisers/

You may consider 10 W to be a waste of time, not enough power. Not so with decent antennas.
10W on HF will get you world wide through sunspot maxima and 10W on VHF goes a long way at times.
I've worked 1000 kms when I've forgotten to switch the linear on, so it can be done.

7372. RE: [loopantennas] Loop Capacitance

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-04-01 11:50:57 UTC
From: Chris Harris
Topic: 7369 Message: 7372

All my loops have fed from the top and tune at the tune at the bottom as the cap is heavy and the feed is not. The feed loop is untuned and the line runs down the centre line of the support pole, keeping everything symmetrical as reasonably possible although I wonder how much the feed loop being unbalanced upsets the symmetry due to capacitive interaction.

Any thoughts on this anyone?

I think you will want to tune the capacitance of your 11m loop as it will be tuning over ~1.2% and you can expect a Q in the 100s if the thing is well built and if it isn't it won't work.....

For you're frequency, a simple DIY variable capacitor should be pretty easy to conjure up as you only need 20pF or so. I have seen cute designs using water pipe or copper sheet or PCB laminate.

First if this is to learn, great.
If this is to save money, bad idea, cheaper to buy it.
You will still need a rotor, controller, coaxial and mast to mount any directional loop....

It is an active or amplified magnetic loop. There are many circuits on the web. The "trick" is they run the DC voltage down the coaxial with the signal.... that is not hard to do, but I am making my own and will have dedicated power to the active circuit at the base of the loop. I just run a phone-line sized two conductor cable next to and with the coaxial. You are running coax, what is two more small gauge wire cable. We are talking about very small current at low voltage.

One trick Wellbrook does, is wide band, with no tuning! How they do that, I don't know. I think it's cool but can cause some issues the wellbrook is known for, and that is bleed from high powered MW (AM BCB stations) into the SW. They make some versions that attenuate MW altogether to concentrate on the upper band. I am making mine tunable. It is a simple controller that varies power to the active electronics at the base of the loop. It tunes a Vari-capacitor, varactor, a solid state version of an air-capacitor.

The loop should be non-ferrite (not iron), copper best, aluminum good. What I am doing is using PVC and running some Litz wire inside it. Done and done, very small loss in bandwidth v copper pipe. Another cheap and good option is make a square loop out of copper water pipe. A loop does not have to be a hoop, although a hoop is cool looking. I would use a 1 meter dia Hoop-loop like wellbrook if I could find one. The best I found was an aluminum hula hoop, used by professional performers. They are about $60 bucks each. A plastic hula hoop with wire in it would be good for indoors, but I think they are too light duty. You can make a wood frame like hub and (8) spokes (octagon) and run a wire around it. This might be good for a BIG 2 meter loop. You get into big loops with copper water pipe it will get too big to handle. If you have room and no neighbors to complain, make it bigger.

By the time you track down all the parts, buy them (with shipping since Radio Shack has nothing anymore and they charge silly prices for parts), it will cost you almost as much as if you bought the Wellbrook to start with. You know the wellbrook will work. If the goal is to save money forget it. If you want the challenge and willing to accept it will not be as good as the store bought, go for it.

To out perform the Wellbrook you need a BIGGER loop.... and that can be done, but than it gets to be something you will mount from and near the ground in a back yard, preferably with out obstacles nearby. This large "sculpture" will be pretty obvious to look at. My home owner by-laws only allow a 1 meter antenna dish.... so a 1 meter loop will do the trick. I am sure they might still complain.

Cheers

RG-58 or LM195 is fine for SWL receiver antenna ... 50 ohms.

Some one mentioned not wanting to use it as it'll create an unbalance feed.
Try using two one each side.
I had used two on the dipole portion of a home built 3 element beam, it's about 39 inches spaced at 3 to 4 inches withwithout capacitors. Feed it using a quarter wave section using rg59 then mate it to the rg58 feeder.
Also I had a homemade swr bridge and a Realisitc 23 channel TRC47 cb. I didn't have access to Internet. A friend from Australia had sent the designs which I simply copied it.

Yes i did use the spreadsheet and i put in 2.5 m length of copper. that gave me a capacitance of 8pf at 27.355 ,but being new to experimenting i forgot to look at the bandwidth,therefore my question.

But i can understand now i need a variable capacitor,and im googling making capacitors.

Re the Ham licence,yes im going there in due course. Ive contacted my local club and they meet the last weekend of every month,except this one cause of easter.

But ive only just started as a cb'er too and i want to enjoy this part of radio while i experiment and learn. Eventually when i get my ham ticket ill actually know most of what im talking about.

I am gratefull to the group for my guidance,its only by asking that ill learn where to find answers,yes theres google but being totally new its hard to understand if google has pointed me to what i actually was asking LOL.

Cheers and TY .. Rob

OK Rob
A word of advise
If your interested in Ham Radio get out of CB.
You will pick up some awful habits which will make having a QSO difficult and you will be judged by
the local Hams as a nerd.
For example , you don't say to the station your working if he is weak and not very readable that he
is in the back of the box, you give a proper report like 4 by 1.

This may sound a harsh but you will find the etiquette used by CBers is not appreciated on the Ham
bands.

So your best bet is not to pick up the bad habits in the first place.
Right as for making capacitors, the easiest route there is to buy one on e-bay, you could make one
out of two discs and alter the distance between them, I'm not sure what the physically largest coin
is in Aus., I have used old British pennies as they were over 1" in diameter, drill a hole through
the center and solder to a piece of M4 brass studding. making sure each is electrically isolated
from them.
But what I think you should do is get a larger variable cap , say 100 pF and tune that loop from
27 MHz to 14 MHz, that will cover Four Ham bands , 14 MHz, 18 MHz, 21 MHz, 24 MHz.
It looks like the Aus foundation licence doesn't allow use of 14 MHz, but does 21 MHz,
Your 10 W will get you some long distances on that band, as it is already starting to open.

Get yourself a radio that you can listen on those bands, and get down to the club at the end of the
month.

You will also be allowed to use 80 mtrs, 3.5 MHz , that should cover all of AUS & NZ.

To avoid using large antenna you can use a mag loop for that band, make it about 2 mtrs in diameter, and with right variable capacitor you should be able to tune between 3.5 MHz and 7 MHz.

Once you have got you teeth into Ham radio, you will not want to go any where near CB.

If as I suspect the Aus foundation licence is very similar to the UK one , you should be able to
get one in a few weeks , then you can really start to play with loops.

Apologies to the others in the group if this is a bit OT

Good luck &
Best wishes

Richard Bown

our local club has classes and testing officers and i believe theres a few classes of licence to entice newcomers through the ranks.

Cb Talk? no i use plain english and ill learn the correct terms in the classes.

No shortage of equipment here,everyone and their dog owns a ham set and theyre relatively cheap too but ill buy one thats not played with through the club so oi get a good one. Cheers Rob

Yes be very careful to get something thats unmodified.
There should be a few TS 830 or TS 530 around, they are hybrids, valve PAs, but have the advantage
they are easy to repair. Some of the newer transceivers can be a pig to work on.

As at first you will be restricted to 10 W , experimenting with loop antennas can be done very
cheaply, you won't have to worry about high voltages across the capacitor, so you can use off the
shelve surplus items.
Out of interest which town/city are you in ?

I ran a B&W (I forget the model number - was is something
like 370-15?). It was great on both TX and RX. It was great
to switch bands with ease. I used it on 80 thru 10 meters.
We compared it with a half-wave dipole anf the dipole was
usually a bit better, but only by an s-unit which is
negligible in my books. The balun blew and I went to an
inverted vee fed with open wire although it would not have
been difficult to build a new balun. Overall, I was very
pleased with the B&W version of the T2FD. Incidentally, at
different times I ran it horizontally, tilted, and in an
inverted-Vee configuration with no noticeable change in
erformance.

WA0TKM,

How'd it work out for you? I plan on installing a stealth antenna on the
roof of a 7-story apartment building soon. Suggestions?

It works well. Use the largest amount of wire (any guage) to enclose the largest area possible and feed it with an auto atu at the wire feed point. Run coax back to the operating position in your shack. As I read things, you will do well from 40 to 10 metres and have a reasonably quiet receive noise level. 80 metres will work "after a fashion" but will not be as good as the other bands. Try working the grey line Dx on 40. Should be good ! Regards, Mike G4HOL

WA0TKM,

How'd it work out for you? I plan on installing a stealth antenna on the roof of a 7-story apartment building soon. Suggestions?

Frank

7386. best places to buy wire for rooftop horizontal loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-04-12 21:03:51 UTC
From: ZephyrNYC
Topic: 7386 Message: 7386

Greetings,

I plan on installing a stealth horizontal loop on the roof just above my 7th floor rental apartment for an 857D, but I need some tips from the experts (YOU). The plan is to go up and install insulated wire all around the exterior walls of the roof. I should've measured it the first time I went up to the roof a few days ago, but I didn't. (It was cold, windy, and brisk that morning; and the rising sun and gorgeous city view distracted me ;) The walls are at least 120 feet in perimeter. This wire would not be visible from the roof of our building unless someone were to lean out over the edge of the roof, or climb up my metal fire escape, which is how I gain access to the roof. Just below the top of one or more of the 4 exterior walls, there is a small "lip" under which I could attempt to slightly conceal small gauge wire if I so desire.

IIRC, insulated copper braid is the best wire for this application. Where are the best places to purchase quality insulated wire (chain and online stores)? I just got off the phone with Home Depot and they sell insulated copper braid that is approximately 1/2 inch in diameter that costs $2.27/foot. Obviously, I can go with a smaller gauge to save money and increase concealment. What is the best way to mount or stick the wire to the exterior walls? Lots of duct tape (less obvious especially if I spray paint or purchase it to match the exterior walls' color, but more risk of detaching)? A number of little brackets and screws (too obvious, but much less chance of detaching)? Brackets and masonry or concrete cement/glue (non-metallic glue)? The Home Depot person recommended as the best method using metal pipe straps screwed into the masonry/concrete exterior walls. I told him that I can't use metal straps because the wire is to be used as an antenna. I also want to avoid creating permanent holes as much as possible. If I do create holes for the straps, I'd be sure to repair them before I move out at the end of the lease. He did say that Home Depot sells plastic pipe straps that cost 69 cents for a pack of 5. For plastic, he recommends one bracket for every 16 or 18" of large diameter wire. However, this would require the use of metallic screws. How much RFI would such metallic screws create? Obviously I want to avoid creating RFI.

Would this type of antenna require a 1:1 or 4:1 balun in order to use an autotuner? If I remember correctly, this type of antenna goes with a 1:1. Thanks.

73,
Frank

Hi Frank
Lightweight wire needs less support and will not change your transmissions to a lower level than thicker wire. For the last five years here I have been using a suspended wire loop made from 1mm ptfe (TEFLON) insulated stranded wire. Results are good. If the wire isn't flapping about in the breeze, I think you can use sticky pads with fold over aluminium clips to secure the wire. You may have to prime the wall surfaces so that the pads will stick." Evo Stik " or any adhesive used for holding down worktop sheets should do the trick. Feed the ends of the wire loop into an auto tuner and run coax back to your rig. Baluns should be placed under birds nests as they can get quite warm. This way you will be doing your bit for nature. I'm just kidding ! (Forget baluns in the auto tuner configuration) The wire loop will radiate effectively on 40m to 10m and possibly on 60m too. The braid you were thinking about is overkill. (How thick is 10 amp fuse wire ?) Because the wire loop is balanced on all frequencies, the prospect of RFI is small.
Good luck mate, de Mike G4HOL

Why have you chosen a loop instead of a dipole (or a bent dipole)?
FYI, a full wave loop will want to radiate straight up (and down).

Rick,

I intend to experiment with a dipole later. My side of the building is the southern side. Right across the small backyard from my side is another apartment building, which is taller. A taller building will obviously block much of a dipole's signal from the horizon, which is invisible from my side of the building. Right next to my building to the east and west are other apartment buildings of the same height as mine. There is another street on the northern side of of my building, with no tall buildings directly across. An elevated dipole on the rooftop would be perfect for north-south or east-west propagation, but would be visible to people obviously. A dipole concealed on the wall on my side of the building would only radiate to the south, which is blocked by the taller building.

A 120' foot loop would be full-wave only around 40m, half-wave on 80, quarter-wave on 160, correct?

Horizontal loop radiation: Straight up on the fundamental certainly ! Lovely lobes at harmonics of the fundamental which become lower and lower in angle of radiation as frequency goes higher. See W4RNL website or google on "CEBIK". Pretty good idea I say.

Read this only if you're truly interested. It's long and boring. I warned you ;)

When I called Home Depot, I meant to say "stranded" and forgot the word, but instead said "braided", so the guy quoted me for braided wire LOL I thank you all sincerely for the corrections. Now I know what to ask for next time.

I'll check out Lowe's too, since I know they offer a military discount, and also the places that you mentioned. A couple of you good hams also offered to sell me some of their extra wire at good discount, which I'll also strongly consider.

I was way off on my eyeball guestimation of the perimeter around the rooftop's external walls last week. I just measured it a few minutes ago-- 332 feet or 101.1936 m around the perimeter, which is now approx. 5/8 wavelength of 160m, 5/4 or 1 1/4 wavelengths of 80m, and 2.5 wavelengths of 40m. What kind of propagation should a horizontal loop of that length hooked up to a tuner be expected to achieve? I'll open up the Antenna Book after I unpack it from one of the many moving boxes.

The most horizon I can see from the roof is to the east, which is almost completely unblocked. (Hello, Europe! ;) I can see the northern horizon but some of it is blocked by other buildings. (Don't worry, New England and Eastern Canada ;) I can't see the horizon directly to the south and west, but the buildings in those directions probably offer less than 15 degrees of takeoff angle till I see sky to the south and approx. 45 degrees to see the western sky. (Sorry guys.)

I didn't find any good attachment points for plastic cable ties. It looks like I'll go with masonry staples, since the walls are made of brick.

I doubt I'll be able to feed the antenna with twin lead because there are only two sets of windows in my apartment:

1. One end of one set (where I want to set up shack) opens up to the metal fire escape, and the window on the other end has a metal grate in front of it. I'll probably feed coax through here. The window frames seem to be made of aluminum.

2. The second window is in the bedroom (where I don't want to set up shack). One side is also covered by a metal grate. The other side isn't, and is the window most distant from the metal fire escape (approx. 18.5'). If my only choice was balanced line, I would feed it

through this window. I plan on purchasing one of the window feed through accessories made by MFJ.

Once again, I thank you all for your help.

Coax is a single impedance cable. When you change bands, the required impedance changes too. - If you use coax make sure it goes to the roof and terminates in an auto tuner. That WILL cope with band changes. Otherwise, take 300 ohm slotted ribbon from the loop through the available route to your shack. A non-resonant loop will give you some great results and I think 160 to 10m is in the bag for you. 10m will be horizon kissing and 160 will be cloud warming. IDEAL !!!

The loop will be "small" on 160 meters which will result
in it having a null in the broadside direction, which
is straight up in the case of horizontal loop. Not ideal
for cloud warming.

7397. Big wheel loop antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-04-14 05:43:53 UTC
From: huf1967
Topic: 7397 Message: 7397

I'm trying to build a big wheel loop antenna to use on a high altitude ballooning project. I've found several websites referring to the popularity of the big wheel antenna but with all the claims of popularity I can't seem to find any design plans. Through piecing information from several different websites together I think I may have some of the design figured out.

What I'm needing to know is how long each element should be. I'm wanting to use this for 144.390mhz with APRS. According to my calculation 144.39mhz has a wavelength of 6.8 feet and if I wanted to make a 1/4 wave antenna then each radiating element would be 20.4 inches long.

If anyone has an information or plans it would be appreciated. Also, once the elements are cut and attached how would you tune this type of antenna or would it even be possible to tune it ??

Thanks !!

This appeared in old editions of the ARRL VHF manual.
I have one of these legacy editions and can scan the
article for you. I remember that it consisted of
three 1 wavelength loops spaced at 120 degrees in
the horizontal plane. I think they were simply
fed in parallel.

Rick,

I would like to get those scans if possible. You can mail them to huf1967@.... I had heard that the plans were in the old ARRL manual but was unable to locate that particular manual.

Are each loop 1 wavelength each or 1/3 of a full wavelength ??

Thanks,
Jay

IIRC, each loop is 1 wavelength. The book is at my remote
base, which I won't be visiting again until April 27, so
I'll get back to you then.

Hi

I have just published an article with some photos of experiments using ferrite rods.

I really appreciate small loops a lot for MW/LW, not just for its practical results, but it's easy to use and we can go everywhere with a portable loop. Well not exactly everywhere, here in Brazil I had some troubles with federal agents when tried to pass airport security with one in my hand luggage

Maybe ferrite looks like old fashioned but it really works for MW dx.

Sarmento;

Nice looking website, antennas and articles!

Two things:
1) Which is the better performer for you - the open loop or ferrite? In terms of gain? In terms of nulling?

2) I use a 2ft open loop (sim to yours) air-coupled to a Twin-Ferrite by CCrane. The open loop is "picked up" by the CCrane ferrite, then signal is sent to radio. One figure eight affecting the other allows for unusual phasing and nulling, and more gain but without more noise. It is a wonderful DX combination although it takes up alot of space. With this setup I can separate two stations about 20 degrees apart - one almost due south and one almost due north. Magical!!

In old vhf UHF books there is a one called a Squalo (not sure of spelling) it is a square loop with a gamma match I believe, built one years ago.

Also I built one from the AntennaX site that looks like a box frame when you are done, I think it was 2 loops made from copper pipe.

The site is complicated to access so I gave it up, something about a new password for every part some interesting designs though.

I have seen a few designs for Transmitter hunting loops (receive only) I need to build one of those.

Good Luck

In terms of directionality and noise which should give the better performance?

A ferrite bar like the Quantum Loop
----------OR----------
The AOR LA-390 1 foot diameter loop
----------OR----------
Crane Twin-coil ferrite

Directional nulling is the most important requirement and noise reduction is next. Gain is not that important and price is not an issue.

I do not have space for anything much larger than these choices and it must be indoors.

Hi Mark

1 ☐ No doubt the open loop. Although the large ferrite loop is similar in terms of nulling, but not gain.

2 ☐ I prefer magnetic coupling, and even when I use pre-amp, I don't use a coupling coil (one or two turn with another variable capacitor to form a LC circuit as usual) together with the main coil. I use a little ferrite rod with a coil and a ceramic capacitor to make it resonate at near central MW band, and than a FET and a small signal transistor to buffer into the receiver's 50 ohm input.

http://www.sarmento.net.br/Acoplador_Loop.htm
(it's in portuguese)

This configuration is easy to work and it's simple as put the preamp box near the loop antenna.

Good find Paul.
Heck, nothing is new!!
But that's OK. I've been told there's a good paper on dual-phasing of loops at the ODXA website. Can't remember what the author called this technique but he had a cool name for it.

Neil;

Sounds like you mean for MW.

Well, to confuse things even more, let's add
Choice #4) Open loop.

What I know: I have a Chinese AOR clone. Gain and null are good but not the best. I'm in a high RF area and the amp has problems with that. I have the CCrane T-F. Gain & null are good but two issues: it is not the best at rejecting noise and the Q is tight - maybe 5 kcs. Good/bad - Tight Q cuts highs (fidelity) but can help 'pre-select' in tight spaces. I understand the Quantum Loop takes no prisoners with variable Q, good gain and tight nulling, but have never tried one. I am very impressed with the open loop / T-F combo i have stumbled upon. See a recent thread here for more info on that. Bottom line on the combo -
Bad: Hogs space, awkward without a lazy Susan, more to fiddle with. Good: Interesting synergies - open loop is my most quiet antenna and seems to keep T-F quiet. Nulling becomes amazingly tight and phasing makes things even more interesting. True improvement in S/N - the combo will make a weak and uncopyable station with any single antenna copyable. No open loop coupling issues because the T-F couples to the radio. And finally - more to fiddle with :)

Hope that helps.

For MW DXing only, the Quantum probably would be best, as it has the Q-tweaking feature to help tighten the tuning and add selectivity.

I have the latter two on your list, both do well at MW, though I find the La-390 generally "tighter" for nulls, and it has the benefit of going to LW and SW/HF should you wish to do that on occasion.

The other nice thing with the LA-390 is that you can also remotely connect the element [up to 5m away according to the manual] using an extension. I have done this with a 4m length of RG174 and BNCs to match the connections on the unit and loop. Gain is not affected significantly, and noise stays about the same. But, being able to orient the loop in a slightly quieter location away from the rig tends to help sometimes. It also helps to minimize wear on the base coneections. THe loop can then be placed closer ot a window, for example, and be slowly rotated [by hanging the loop off a curtain rod, etc.]

Another possible option is to get some thick ferrite [for MW/160m] from Stormwise dot com and wind your own loop with some litz. Not hard to do, and you can tune it with a variable. This is VERY quiet, and even running a preamp outboard of the antenna, it is really "tight". I use a 13.5" x 1" ferrite rod, 125u type.

7422. Broad band receiving loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-04-18 13:22:46 UTC
From: markthomasq
Topic: 7422 Message: 7422

Hi everyone

Ive put up a vertical loop antenna 10 foot verticals and 12.5ft across (basically a small flag antenna without the resistor.) fed by a 9:1 balun (bottom corner) it will be used for general sw listening.
(broadcast bands)

The flags I use are always fed by a 16:1 balun and are of similar dimensions. Ive seen reports of a similar antenna used for sw with a 4;1 balun.

I was wondering which would by the best balun "value" for this antenna. I will be putting a resistor pot in the opposite bottom corner when resume MW (am) dxing

The antenna compares favourably with my vertical for 40m (33 foot vertical wire) better on the upper bands not so good on 7mhz or 6 which is to be expected I suppose.

Any advice on the balun or recommendations for a better low noise antenna

Also are there any designs for a loop for 17m Transmitting
Thanks very much

Mark

Hi Mark,

I have nothing definitive to tell you regarding the best balun value(s) for a receive loop antenna. I can only tell you that I use 9:1 baluns on my receive loops, but being curious, I have substituted a 4:1 balun and found no significant difference in noise pickup or signal levels. I suspect that for receive purposes it is not terribly critical.

Purists will cite impedance characteristics and transmission line losses but I have found receiver front ends to be very tolerant with regard to matching. The largest contributing factor of the balun, in my opinion, is that it provides isolation from the outside surface of the coax feedline, and this contributes greatly to less local noise pickup.

My modest receive loop adventures are detailed at the link below. My vertical triangular loops are oriented so that one favors N-S and the other favors E-W reception. They are quite bi-directional from 400 KC to 5.0 Mhz but receive very well without a distinct directional pattern up through 20 Mhz. Being located away from the house, they are very quiet compared to my station dipole antennas. They are basically very simple K9AY sized vertical triangular loops without any terminating resistors or control circuitry.

7424. Question about changing antenna tuner from 27Mhz spectrum to SW bands

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-04-18 18:31:01 UTC
From: marc
Topic: 7424 Message: 7424

Hello,

I found this antenna tuner that seems to be for the 27Mhz band.
Here some pictures
http://users.fulladsl.be/spb13810/research/antennatuner/

If I adapt the spool (more turns) it will tune lower than 27Mhz.

I could put in a slf made spool, and then slide a ferrite bar through it
as well, to tune that part of the tuner ....

This is an antenna tuner for TX, not really for TX, but what would the 2
variable capacitors do?? (the word "balanced" comes to my mind...) I'm
"used to" ONE variable cap, and one spool ...

Other suggestions?

I can hang a loop antenna on the input, or some other "simple" vertical.

Thanks,
Marc

take the coil out and rewind one for 10 turns at 1.5" diameter. Tap the coil as needed.finished.

HI Marc
in addition to the tapped coil, you might also want to rewire one of the variable caps in series with the coil . That wou;ld mean insulating it from the chassis, but would make the tumer more versitile.

7427. balanced line & metal-framed windows

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-04-22 21:31:34 UTC
From: ZephyrNYC
Topic: 7427 Message: 7427

Hello, everyone. Does anyone in the group feed an outdoor antenna with twin coax or regular (non-coax) balanced line going through a metal-framed window? If so, what kind of problems do you experience? AFAIK, using balanced line near metal is a big no-no, but I read this today:

Regular balanced line:

http://www.mail-archive.com/elecraft@.../msg30984.html

"... you can cross a metallic boundary with parallel feedline with no problem to the RF as long as it occurs at right angles to the feedline - again be careful that you have adequate insulation where you cross, the RF voltages can be quite high even with low or moderate power if the feedline has a high SWR."

And this on balanced (twin) coax:

http://eham.net/ehamforum/smf/index.php?topic=66987.0

"I would like some advice on feeding 450 ohm window line at right angles through aluminum siding. It's the only way I can do it! Can I get reasonably close at this right angle? or do I need several inches around etc."

"If you want to be entirely safe about it, you could change the ladderline to two side-by-side coaxes for the short final run through the siding and to the shack.

Connect an inside conductor of each coax to each of the balanced line conductors.

At the balanced line side, connect both coax shields together and solder. Insulate all three connections from each other well, using weatherproof tape or something suitable.

At the shack end, connect the two center conductors of the two coaxes to the balance line connects. Connect the two shields together and also connect them to shack ground.

This will create a shielded, balanced line that can cross conductive metals without problem. You could pass the two side-by-side coaxial cables through the siding through one tight pass hole or two, doesn't matter as they are now shielded but still running in blanced mode.

Old trick that works."

More on regular balanced line:

'But seriously, I'm sure you've heard that you have to "keep
ladderline several inches from metal."

Right angle crossings don't really count.

The important thing with keeping ladderline away from *metal* is that
you don't want to run it for a long stretch close to and in parallel
with a third unbroken conductor, because that turns it into a
different kind of feedline, one that has a lower characteristic
impedance and generally one that has more loss in the situations where
people like to use ladderline. So that's what you want to avoid.
And if you ran it very close to a long stretch of lossy, damp material
like dirt, the way the fields interact with the dirt would cause a lot
of very direct loss.'

More on balanced (twin) coax:

http://forums.hamisland.net/viewtopic.php?f=4&t=4793

Aside from differences in shielding, weight and cost; what are the
pros & cons of using balanced coax vs. regular balanced insulated
line?

Does RF from balanced feedline really cause interference to pacemakers
and other medical devices? I am curious because my apartment window
frames seem to be constructed of aluminum, and I have plans for an
antenna that will probably need a long feedline. The two windows are
approximately 4' and 15' from the edge of a metal fire escape.
Thanks.

>today:

I have used balanced feed line 600 ohm home brew, 450 ohm, 300 ohm Twin lead, 75 ohm Twin lead (no longer available), and never had any problems with any of them. Most people don't remember that TV twin lead was designed for VHF use and was connected directly from the antenna to the receiver on millions of TV sets with no problem. If it could handle VHF it certainly won't have any difficulty with HF.
Standard techniques .... if running parallel to metal objects .... like a tower .... keep the line at least 1 ft away (2 ft is better). On these parallel runs it is a good idea to put a few twists in the feed line.

Crossing a metal barrier .... such as a rain gutter, or a window frame does NOT create an "RF" problem. I have used a number of different feed-through solutions. 1. make the hole big enough for twin-lead to go through. Make sure there is enough insulation around the portion going past the metal. You can transition from 450 ohm to 300 ohm back to 450 ohm with no difficulty ... just be sure each piece is balanced line. This system works fine in the 100 - 150 watt range.

When dealing with high power then the feed through technique is different ... just like feeding the stove AC power is different than your floor lamp. Same kind of AC ... just more of it hi hi. A technique I have used for high power is to construct 2 parallel insulated feed through's using ceramic fittings (harder to find these days) with a center copper rod in each with nuts and washers at each end. Then simply connect the outside parallel line to the outside connectors and the inside parallel line to the inside connectors.

It is simply a mechanical problem. You will have to size up your own situation .... and walk up and down the isles in Home Depot until you see something that will do the trick !!

>Regular balanced line:
>
><http://www.mail-archive.com/elecraft@.../msg30984.html>http://www.mail-archive.com/elecraft@.../msg30984.html
>
>"... you can cross a metallic boundary with parallel

>feedline with no problem to the RF as long as it occurs at right angles to
>the feedline - again be careful that you have adequate insulation where you
>cross, the RF voltages can be quite high even with low or moderate power if
>the feedline has a high SWR."

By definition the line will have SWR .... but if the antenna being fed is very short in relation to the wavelength of the RF being sent to it there can be very high RF voltages. However if the antenna is 100 ft or more the RF voltages will usually be manageable at all HF frequencies. However as you move up in power you will also have to be sure all points will handle potential RF voltages.

For example if you feed a 32 FT dipole on 40M you will get by if running QRP. At 100 Watts you will put a strain on the feed line as well as the balanced tuner. At 1000 watts ... forget it hi hi.

In my view the only reason to go to all the trouble of converting parallel coax cables to balanced feed line (also questionable whether there is RF shielding) is that running the parallel cable next to a metal object or through metal conduit a considerable distance it is unavoidable. Going through a wall is no problem. I have done it both commercially and in Ham radio with very high power ... with no problem.

Hi,

Another technique I have used is to drill 2 holes through the frame a couple of inches from each other. Then push plastic tubing through the holes so that the tubing is flush on both the inside and outside surfaces. Then get appropriate diameter threaded brass rod to run through each tube .... e.g. 3 to 4 inches ... depending on the thickness of the window frame ... wall ... etc.. Washers and nuts on each side for fastening the parallel cable. Ceramic tubing was common a long time ago. However check out Home Depot ... I am sure you will find all you need hi hi. It will make a nice neat feed-through.

Welcome. Let's start by finding out what frequency bands you are most interested in and if your antenna is portable or permanent. That would help in determining what antenna can suit your needs. Try also to search on Loop Antenna and it will also give you many references. Most of them are focused on the Medium Wave (MW) band, but by changing the size of the loop or the number of turns, something may suit your needs. Keep in mind also that band conditions normally change during daily and yearly cycles and where you live so things may not always work the same.
I have taken my ATS-909 on travel but have used a Terk Advantage for MW (530-1710) reception in the States and the ATS-60 portable reel antenna supplied by Sangean or a simple dipole when traveling internationally due to weight limitations and short term of travel (business).

Hello, I am new to the forum. It is looking very hitech to me!! I do not know much about antennas. I have a Sangean ATS909 and I want to bring it with me where I work in the south of Sahara desert (Hassi Messaoud, Algeria). I would like to be able to receive radio from France. Hassi Messaoud is located approximately 1300 km south of Marseille, 2000 km south of Paris. Any recommendation of what can be done here? The radio has a 3.5 jack input for an external antenna.

Thanks for any help.

Laurent

Although some may poo-poo them as not being a "real" antenna (whatever that is), you can find the "slinky" antennas on eBay which naturally are compact and durable for travel. I use one for my ATS-909 and it works well. Also any reel antenna or even just a wire 6-7 meters long or longer will work well - you can just put clips on the ends and attach to the whip antenna and to any elevated termination. Either of these will give you much improved shortwave reception and are cheap and easy solutions for travel. For AM broadcast band reception the Terk Advantage will work well and is reasonably compact and inexpensive.

Topic: 7434 Message: 7434

Hi all
How susceptible are mag loops to foliage on trees ?

My 4mtr diameter loop I use for 80 mtr has now refused to resonate, sweeping it from a sig gen there seems to be a slight resonance at about 5 MHz.
It was placed between a Magnolia bush and a cherry tree, to please the XYL, sort of semi hidden, if you can hide something that size.

I was going to build a return loss bridge, and did'nt get a round to it, now I wish I had !!

I never have a problem with my trees and resonance of my 80M magnetic loop. Only time I did was due to rain water on the UHF connector before I weatherproofed it.

Readjust the matching section for low SWR and retune.

Surrounding objects will affect the impedance but adjusting the matching section will always compensate. The end effect will be slightly less efficiency but you can live with that.

Thanks Tim for your input. As I mentioned I know nothing about antenna. My radio was provided with an external wire that is 7m long approx and that is rolled inside it's case. I was looking at it as a cheap and maybe inefficient device since it was not looking a like a proper antenna.
I will then use it and try to catch frequencies of French radio there. Thanks again for your help.
Laurent.

Anybody have a car set-up? Maybe a rectangular look on top, outside or inside? I'd like to use my portable receiver in my car. I've tried wrapping a little wire antenna around the roof on the inside...I can actually get better-than-whip response. But I'm think a loop would be better.

Anybody??

Try this : one short ferrite bar whith some wire coiled on it and connected to the antena input of the receiver.
Then the ferrite is placed transversally to one of the car´s door frame.

Or easier : put your portable near the frame to couple it directly to the internal ferrite (if your portable has internal ferrite antenna)

It works for medium wave.

Correction : the wire coiled in the bar must be conected to the antenna and ground of the receiver, with a short lenght of coaxial cable, or a pair of wires.

Thanks Jose!

I don't have a ferrit bar lying around. I've seen talk about the CCrane(?) ferrite bar.

So let me ask...you get the bar, put it flush against the metal car body (e.g., against the roof on the inside), and connect the ends to the receiver antenna and ground.

That seems like it might work. I was thinking about an active loop...buy I'm sure my wife wouldn't want it on top! I think it would be kinda cool!

Hi,

An old ARRL antenna handbook (1950's vintage I believe) shows a loop arrangement for HF mobile. basically 2 grounded vertical antennas bent over and coupled. It can be fed at either ground point. It has a short ... 1 page discussion on its characteristics and efficiency. the major problem is the efficiency; with the very low radiation resistance the antenna coupling is very critical vis-a-vis efficiency. However, unlike a loaded vertical antenna a lossy loading coil is not needed as the loop is tuned by a series capacitor. As with all small loops the loop construction and feeding is critical if any amount of power is to be converted to electromagnetic radiation.

PS... my last posting dealt with a HF transmitting antenna
arrangement. the arrangement would work quite well for receiving ... as
the loop would be tuned with a single capacitor ... which could be located
at the front panel of your vehicle.

I was thinking of making a loop antenna using copper foil. My understanding is that 100mm copper foil would be equivalent to 50mm copper pipe. However there is some talk about 'current crowding' at the edges of the foil. There is a reference in following document that I would like to follow up:
http://midnightdesignsolutions.com/MidnightLoop/Midnight%20Loop%20(Mar%2011a).pdf
And the reference is to:
Resistance of Foil Conductors For Antennas, Rudy Severns N6LF, QEX May/June 2002 Tech Notes
Maybe someone could scan that for me?
I have some interest in maximum Q loop antennas. There are indications that a 2 turn foil antenna would be best in that regard. However it is all very complex because of the proximity effect and distributed capacitance etc.

Sean,
I have had very good luck using a strip of copper flashing for a loop
element as far as efficiency goes. One thing I did find out is that
a copper foil loop will not hold up very well if placed outdoors.

If placed outdoors in the open the wind tended to catch the strip
and it would twist and vibrate in the wind and eventually fail due
to metal fatigue.

For an outdoor antenna I would only recommend using round
copper pipe as it is very rigid compared to the copper foil and
will stand up to the wind and weather much better.

For an indoor or attic antenna a copper foil loop should work
fine as long as it is held up by a rigid framework with good
insulation. I would stick with a single-turn loop.

Remember skin effect and use copper foil 10 mils thick or thicker
for lowest RF resistance.

You can also use as length of heliax it nearly self supporting, LDF 4-50 is

equivalent to 13 mm because of the ridges in it, but the nice thing is it an interference fit inside 15mm Cu tube, the same as 1/2" Cu tube, so yoiu can make the loop an strip back the outer cover and stuff it up the 1/2" tube so you can use ordinary pipe fittings,
There is always a good supply of LDF4-50 , just ask any of the VHF/ UHF Dx guys, they may have a piece long enough for your needs./
ie a length that water has got into, once that happens its pretty useless as coax ,but it doesn't matter for building loops as you are using the outer copper cover. It will also handle power.

I've used 1/4" self sticking copper foil used for stained glass work for quick magnetic loop antennas setup in hotel rooms. These run aorund $5 for a 60ft spool. I would run the foil along the hotel window spaced several inches inside the metal window frame. I used gamma matching at the bottom of the loop to match to the coax and a wide spaced air variable capacitor at the top where I split the foil. Using a battery operated soldering iron I tack soldered the wire connections to the foil. I also keep an assortment of capacitors in my bag in case I need to pad the tuning cap. Using up to 20 watts I worked 20-40M CW with good results. I've even worked as low as 80M if the window was large enough and also had surprisingly good results. When ready to check out of the hotel the foil comes off the window easily with no residue and I discard the foil in the trash.

Stealthy and effective!

CQ magazine for April 1967 has an article "Skin Effect in High
Frequency Design". I quote: "The values from the graph (fig. 1)
represent the depth at which currents will be reduced to 1/e (where
e=2.302) of the surface currents, and it is customary to provide for at
least 5 times the skin depth shown. For all practical purposes, 5 times is close to 100%
conduction." The graph with the article is quite small,but it looks like the basic value
for copper is 1 mil and for
aluminum, 2 mil. So if I interpret this correctly and the article is
true, 5 mils would suffice for copper, and 10 mil for aluminum. That
would seem to make copper foil usable. Aluminum foil, I suppose you
would have to use a much larger width to lower the overall AC resistance. I have thought
about making a loop from plastics plumbing
pipe, and then somehow covering it with copper foil, like maybe a couple
lengths stretched along the whole length of the pipe, the loop being
built in a square. I wonder how solderable this copper foil is, if at
all. I found my two rolls of copper foil in a garbage dumpster after
some kind of constructon job (we have a very wasteful country) but I
think it is also sold for use in stained-glass hobby projects. Aluminum foil comes in
widths up to maybe 18 inches and not expensive at all
so maybe it could be used somehow. You would have to build some
kind of box-like framework to attach it to, something looking kind of
like a box kite. -Hue Miller / Newport, Oregon, USA

The foil I found in the trash is 2 inch width. Pretty nice stuff. Interesting the idea of the disposable loop antenna using narrower stuff. Now re "current crowding", back around the late 1970s when AEA (company) was offering a loop antenna built on a metallic band or stip, this may have been the reason MFJ company touted their loop antenna as being more efficient than a model not using a cylindrical conductor. Now that AEA is gone, I don't recall seeing MFJ advertisement text that still claims this advantage, since there's not really any competition. -Hue Miller

It occurred to me that I could try a "proof of concept" experiment by
taking a large cardboard box from a moving company, and running a strip
of aluminum foil around it. That would be a strip around 12 inches or more wide. I wonder
if she high voltage developed would be a fire hazard
with the cardboard? At least it would be safe at low powers. I recall
once many years ago, trying to run a 80 meters, 100 watt transmitter
into a short indoor antenna, made of aluminum foil by the way, and
setting the window curtain on fire, from the high voltage flashover.

Your local home improvement store probably has copper tape as "slug tape".
The adhesive isn't conductive like EMI/EMC tape from 3M, but it's a lot more
available.

Hi Andrew

A great idea. I'm going to practice on the front picture window! By the
way ... who caries the copper foil tape ?

Thanks,

Jim, VE3CI

I bought several foil rolls on Ebay but they can also be found in arts and crafts stores that carry stained glass supplies. I found some locally after I bought mine on Ebay.

re; cardboard and fire: unless the loop arcs over somewhere or there are metal particles in the board I wouldn't worry about a few watts of RF. Personally, I'd avoid the cardboard anyway. It reminds me of the Harry Lythall SM0VPO packing crate loop antenna:

I would just like to clear up 2 common misconceptions:

1. Tubing vs foil (or any other non-close shape):
RF current spreads out on the conductor and concentrates on
the edges. Tubing has no edge, therefore the RF
current will spread out more uniformly. If the tubing
is circular (as opposed to square) the current is forced by
symmetry to be uniform and there is no current crowding.
This is why round tubing will have the less loss than
foil of comparable dimensions.

2. Reducing conductor loss in a small loop ultimately results
in an impractically high Q with very narrow bandwidth. If
you are stuck with a small loop, it just isn't going to be
very efficient and there isn't a lot that you can do about it.

Summarizing: foil will be lossier than comparable tubing.
It may not be much better than wire. So your foil loop will
not be especially efficient. OTOH, if foil is convenient to
use, go ahead, because loop efficiency is much more about loop
size than conductor size.

Andrew,
I'm still studying loops at age 65, but dense in abstracts and terminology. I assume you are referring to matching impedance of the loop to your transceiver when you say "used gamma matching." Try to use concrete terms to explain and show what you did in gamma matching. I can't visualize what you did.

I found on amazon.com JVCC brand 36 yard by 1/4, 1/2 and 1" 1 oz (thickness measure) tape with conductive adhesive (USD $12, 22, 39 respectively.)

http://www.amazon.com/JVCC-CFL-5CA-Copper-Conductive-Adhesive/dp/B000WQBRJA/ref=sr_1_3?ie=UTF8&s=hi&qid=1272817726&sr=1-3

Maybe it is used in laptop display repair (for shielding the inverter and fluorescent lamp circuitry)?

Not known if it can be cleanly removed from window glass...

Another one - 2" wide tape (thickness unspecified) also 36 yard roll, however, it does include in description text "it's aggressive adhesive system..." so maybe not so easily removed? Anyway, USD 49 per 36 yard roll makes interesting possibility for wrapping lengths of PVC (not sure if it would survive outdoor flexing and getting around 45/90 degree angles...)

7459. Wellbrook or RF systems

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-05-02 18:41:32 UTC
From: enriqueeeeee2001
Topic: 7459 Message: 7459

Hello Group,

Recently I have sold a Wellbrook 1530+ antenna, I have been using it for two years with good results. I have moved home and two strong stations on MW creates intermodulations in the receiver.
So, I have been thinking about a replacement for the 1530+ , Wellbrook 330S it is good for shortwave and do not produce intermodulations because it is more attenuated on MW.

I have read some reviews about the RF systems DX one MKII, it is said that its perfomance is better than the Wellbrook. Does it need a good earth?

My questions:

Is worth buying the Rf systems instead of the Wellbrook?Any significant improvement?
Would I pick up much more weak stations, clearer and with less noise?
I am mainly intereested in listening weak stations on tropical band, so a good antenna it is important.

I would be very grateful if somebody could throw some light about this difficult election.

Thank you very much
Kind Regards.

Why go through the hassle? Wrapping copper tape on a PVC form leaves you with a fairly stiff loop, and alot of unknowns.

"Air con" copper tube (available in multiple sizes at any home supply or plumbing house).

Thin wall copper pipe, easy enough to make an octagonal loop with a couple sticks and some 45 elbows.

If you want flexable/portable there are a number of receive only designs that used coax. You could also use a fine strand DC power cable, #4 can be had that rolls up almost as easy as rope.

Losses would be higher, but I suspect losses would be lower in #4 power cable than with copper foil wrapped on a PVC form.

Don't get me wrong, the copper foil trick is neat for a temp antenna, used in myself on 6M once I just would not use it for a high current low band antenna where I had another choice.

I would purchase or make one or two filters to block/severely attenuate
the MW band first. I am mostly interested in NDB's below the MW band and
use two that do a good job. Both were home built. Both have in/out
switches built in.

From: sean
Topic: 7462 Message: 7462

I wrote a PCB magnetic loop antenna calculator a while ago:
http://lemontree.googlecode.com/files/PCBAntenna.zip
I based the maths on the reference that is included in the zip file.
I doubt the results are terribly accurate, just back of the envelope figures. For example it does not include dielectric losses from the PCB material.
Anyway you can play around with it and see how the different parameters interact.

Thanks,

Yes I have already sold the 1530+, I was using it with a Racal 1772
receiver.
The 1772 has a RF tune, is like a preselector, it works excellent. I can null
the Am interferences, but it is very tired adjusting the potentiometer everytime
you move of frequency.
I am also interested in AM and LW Dxing, so before buying the Wellbrook 330S I
would like to know if it would be better the MK II. How is the perfomance on HF?

I have read some reviews about it and it is said that it needs a good ground,
Would I have better catches, regional stations?

Thank you for your help.

Well, the Wellbrook is a loop so you have the possibility to null out interference or noise. The DX 1 is omni. I have not put a ground on my LFL1010. Sometimes grounds will add noise. Everyone's situation is different - I am happy without it.

I logged 62 new NDB's the first 30 days after I installed the LFL1010. I believe this is due to the lower noise floor. I wish I had not been so cheap and got one before. I think the Wellbrook loops are pretty much the same - some are supposedly optimized for certain bands.

I don't know much about the DX 1 other than it is an active antenna and will be noiser but you may not notice that on SW bands. Also you don't need a rotator. I also think it is better to have a vertical active antenna, a loop and a wire antenna. Each responds differently to signals. I recently took down my wire antennas a couple of years ago in favor of the PA0RDT Mini-Whips though. The wires only problem was that they were ugly on my small real estate!

From: enriqueeeeee2001
Topic: 7459 Message: 7465

I have got also a PA0RDT Mini-whip, but no significant improvement, too noisy for my taste. As well I have a PAR end-fed it is a good antenna but the Wellbrook outperfoms both of them.

I am still thinking about the Wellbrook 330S, I have mailed Mr Andy, the owner, and has told me that the 330S has 4db gain from 4Khz but it is attenuated on MW and LW.

Since I am also interested in MW Dxing, I think that with a good preamplifier I could solve that attenuation.

Regards.

Enrique,

If you let me know the power and the distance you are from the two MW stations I can work out whether the ALA330S would be suitable.

Kind regards

Andrew Ikin

Get the 330S. Who said the RF Sys was better?

Passport## rated these two antennas.
330S **** - FOUR STARS
RF Sys DX1 Pro Mk II ***1/2 - THREE HALF STARS

2006 Edition - can get it on Amazon I think new or used. Get it and read the review. The Wellbrook is excellent.

The RF SYS Con was:
unbalanced design susceptible to buzz (mag loops excel in noise reduction)

AC power supply hum albeit slight

More likely to exacerbate signal fade

6 Month Warranty

Get the 330S. Who said RF Sys DX Pro II was better?

Passport 2006 edition reviewed both. You can buy a copy of Passport used or new, 2006 editon on Amazon I think. That is where I got mine. Read the reviews.

The 330 got FOUR STARS
The RF Sys DX 1 Pro Mk II got THREE and Half STARS.

The CONS for the RF Pro Mk II:

Unbalanced antenna design more susceptible to importing buzz (local noise) (Note: magnetic loops like the Wellbrook are better in rejecting local noise.)

AC power supply gave slight hum

More likely to exacerbate signal fade.

+10dB gain setting was actually +6dB gain

6 month warranty

I would not believe everything you read, as I have the DX1 PRO mark2 and also the 1530+ and I can assure you, that the DX1 can hear a lot more than the Wellbrook.
The only advantage the Wellbrook has is nulling out noise and interference.
Importing buzz and local noise re: the dx1) Passband said it "could", not, that it "does".
If you have the DX1 earthed correctly it is as quiet as the Wellbrook.
"More likely to exacerbate signal fade"."FIDDLESTIX", to be honest the 300' longwire is worse. On a given day the DX1 holds a better DRM signal than the longwire

Lastly, I would never sell the DX1 PRO MK2, if I had to sell any of them I would sell the Wellbrook, but in saying that the Wellbrook is a great antenna, but not as good as the DX1.

Cheers and regards David

7471. 80 meter folded dipole VS loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-05-06 17:34:43 UTC
From: james
Topic: 7471 Message: 7471

The shape of my back yard can accommodate either one, but I am leaning towards a folded inverted V. from what I seen online googling for folded-dipole designs they look like a loop that was squashed in to a dipole configuration, I have a 4:1 balun I will be using at the feed point (fed with 50 OHM coax) when I put it all together,

I also have a 50 OHM terminator resistor to use where the ends of the dipole come together making a loop, (not sure if I should use it or not)

I have an auto-tuner for 80, 40, 20 & 15 so SWR wont hurt the radio, I just want some resonance so it will RX/TX well (after spending big bucks on a HF rig I cant see going without a auto-tuner for protection)

Hi,

First, a folded dipole is NOT a loop ..... it is a dipole. As with any dipole it can be configured in a Vee configuration .... usually because it is easier to do than a horizontal version ... one support etc...

The antenna currents in a folded dipole are equal and exactly in phase along the total length of the antenna. However, because the current is divided equally in the two wires the current at the feed point is one half. Using simple ohms law this then converts the input impedance by a factor of 4. If the impedance of any particular traditional dipole in your location ... given height and ground conditions etc... was 70 ohms .... then the impedance of a folded version would be 4x70 or 280 ohms. there is no reason to put a termination resistor at the ends.

If you plan on using the dipole for a single band then cutting the antenna length to 1/2 wavelength will do the trick and it will represent a satisfactory match to 50 cable in the traditional format ... and a suitable match to 300 twin lead in the folded configuration. However if you plan on using the antenna for multiple bands then you will have a non resonant condition on most frequencies and complex impedances. the twinlead will be a better choice ... whether you use a traditional dipole or a folded dipole.

Jim, VE3CI

You're right!

Thanks for the reply, from looking at images and diagrams of folded dipoles they looked like a squashed loop, but after reading some info at Wikipedia I see they don't make a connection forming a loop (they just come close) = solved that mystery.

From my experience loops seem to be quiet yet still get good reception and HF can be quite noisy, I have built a half wave delta loop fed at the apex and so far it is working nicely.

If only you could erect a full wave, say 283 feet circumference, and feed it with 300 ohm slotted ribbon, tuned up in the shack, it would shine from 80 to 6 metres. Horizontal layout gives amazing results and low noise on all bands. Big is beautiful!!! Mike, G4HOL.

Actually, most folded dipoles are wired exactly like a loop. If you start with a loop and squash it flat, you would end up with a folded dipole exactly. But this act of squashing it, makes it behave totally differently. The currents redistribute themselves and the pattern changes a lot.

I haven't seen the Wikipedia info, but if it shows the folded dipole with the ends NOT connected together, that is one way you CAN do it, but most often the ends are shorted.

There is this notion of capture area for an antenna (the more the better), and it would seem like opening up a folded dipole into an open loop would increase capture area and make the antenna more effective. In other words, maximizing the use of your yard's space, in area not just linear space, MIGHT be a good thing. But I think the difference is actually small.

Loops and (folded) dipoles have rather different directional characteristics, as well as bandwidth, and usefulness on multiple bands, and those should also influence your decision.

For example, a (folded) dipole's pattern looks like a donut, but a full size loop's pattern is more like back-to-back flashlights. Thus the loop might give you less "wasted" power going in directions you don't care about (like straight up or down if you only want to do DX).

Both loops and folded dipoles (with both ends shorted so that it forms a loop) do have the advantage that static voltages won't build up across the antenna terminals, which makes them quieter in the wind or rain.

Andy

Yes, but there is a big difference....

In a loop the difference in the wave causes the current to flow in one direction on one side of the loop, and the opposite direction on the other side of the loop, because the two sides of the loop are being intersected, and magnetic wave cut on a different part of the wave.

But with a "folded dipole" both sides of the "loop" formed are too close together, and the signals are going in the same direction. The other half of the "folded dipole, that is, the half not connected to the feedline, is wasted. It has the same currents and voltages as its parallel portion all along the wire. So no current flows from the feedline half to the other half and vice versa. The voltages out on the ends are the same, and have zero current flow.

I have made folded loops and then cut them at the ends, and it makes no difference. The other piece of wire is wasted.

> Yes, but there is a big difference....

Indeed there is. What I described above is just the physical topology, that the wires of the folded dipole do trace out a flattened loop. But as an antenna, the folded dipole behaves nothing like a loop and everything like a dipole ... with the two exceptions that (1) its feedpoint impedance is quadrupled, and (2) it has DC continuity.

Like you say, the current directions are those of a dipole.

> The other half of the "folded dipole, that is, the half not connected to
> the feedline, is wasted.
...
> I have made folded loops and then cut them at the ends, and it makes no
> difference. The other piece of wire is wasted.

I'm not sure exactly what you're saying, if it's how I'm reading it ... but it isn't wasted. Yes, you can cut the bridges between the two wires and THAT won't make much difference, but it's not the same thing as removing the other (now disconnected) wire. That other wire has a significant effect; it is quite tightly coupled to the fed dipole wires. It causes the terminal voltage across the other wires to double, and the current to be halved, for the same power. So the feedpoint impedance quadruples. Big change.

Does it improve antenna gain, or reception? No. But it is most useful to move the impedance upwards. For a low horizontal HF antenna, that is an important matching technique. Also for FM radios, to transform the 72 ohm dipole impedance up to the radio's 300 ohm input impedance.

And as a side effect, it widens the antenna's bandwidth a bit, just like a cage dipole does, because the antenna is effectively fatter.

It's worth remembering that the folded dipoles we're talking about shouldn't be confused with T2FD's, which employ a terminating resistor(s) to achieve very wide SWR bandwidths while sacrificing efficiency. It's a different animal.

I'm looking for a podcast/podclass for the Technician Class amateur radio license, something I can listen to at work that -DOESN'T- require iTunes or other 3rd party installation, just whatever comes in IE/Windows.

I've found higher class podcasts, and those requiring iTunes.

Thanks,
 Steve Greenfield

7482. high vswr

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-05-13 11:51:16 UTC
From: richard
Topic: 7482 Message: 7482

Hi
My 4.5 mtr diameter loop works very well when tuned with a high C:L ratio.
Its tuned with a 10 -100pF vacuum cap, and I'm using a vacuum relay to switch
in a 390 pF door knob cap to resonate on top band.
On top band it covers 1.980 - below 1.8 MHz, the bandwidth without tuning is
only about 1 KHz.
With the 390 pF cap switched out it covers 3.650 - 7.730 MHz.
Across top band the VSWR is very low , and the same with 80 mtrs, but If I
wanted to use 5 MHz the SWR is creeping up still very usable, at 7 MHz its up
to 1.8:1 then rises to 2:1 at 7.1 and 2.5:1 at 7.2 MHz.

I'm guessing at 7.2 MHz the tuning cap is about 15pF, allowing for the stray
capacitance of the wiring in the head unit. The whole thing is remotely
controlled.
Would I gain a decrease in the SWR if I reduce the diameter of the feed loop ?
or is this normal behaviour, and ignore it.
I don't want to screw up the performance on top band.

TIA

--
Best wishes

Steve, go to

http://www.w5ddl.org/

and on the left side of the page you will see classroom presentation (PowerPoint) for Tech, General, and Extra. From doing the Tech Powerpoints my practice test scores were bumped up from 80%-85% to 95%-100%. I scored 35/35 when I took the actual tests.

You will need PowerPoint, or at least, a PowerPoint Viewer. You will find in the Tech presentation a link to download the free PowerPoint Viewer. You may or may not have this as part of your MS Office Suite. No matter, a free download.

These are excellent, and I urge you to download the presentations and work on them, two chapters a night, and at the same time, take some of the practice tests to be found at QRZ.com, eHam.net, etc.

Once you get your practice tests over 90% for the Tech, begin studying for the General, too, while continuing to study and take practice tests for the Tech. And if get your General scrores up, begin on the Extra.

The General opens the world of HF to you, and is a lot of bang for the buck. It is really not much more difficult than the Tech.

I don't mean to sound as if bragging, but I took and passed all three tests in one sitting. Others have done the same. Don't shortchange yourself. Aim high.

At 4.5M diameter your loop is 46ft in circumference which is quite large for 40M. The best you may be able to do is get a compromise SWR across all 3 bands if you modify the feed loop.

I would be happy with using that loop on 80 - 160M with that low SWR and perhaps a second smaller loop for 40M and above. Either way with a 2.5 SWR on 40M you will still have an effective signal.

Hi All,

If you tried to price the cost of copper lately, its clear that for an economic solution to the truely efficient magnetic loop antenna, a non-copper support of the loop makes sense. Really, to get good efficiency for middle HF frequency (7 to 15 MHz), a three inch diameter copper tubular conductor in the 3 to 4 foot diameter range is a good target.

A tubular conductor that size from copper, or even aluminum is very heavy, and will require some significant mechanical design.

A PVC octagon made from 3 inch or 4 inch lightwieght (not the solid) PVC tubing is a reasonable cost.

If one then, rather than wrap the copper flashing, but laid it side by side in-line with the PVC support tube , a low resitance loop could be made. The issue with wrapping , is that the currents flow in the direction of the tubing, and every time a current has to jump to the next layer of wrapping, it incurs a resistance. So, a wrapped configuration would require soldering every wrap-to-wrap joint, and then you still get the solder surface resistance. By having the conductors in line, with say a tack solder here and there, much less resistance is encurred.

Now, current bunching is an issue, but I have not seen any modeling to suggest how much of issue at HF. The practicalities of the flat loop may just not occur until much higher frequencies. Or maybe not. Without any true high frequency analysis, its just not clear how wide the strip has to be before the current bunching increases the resistance by what percentage over the predicted surface area resistance. Indeed, what modelling I have done on this issue tends to indicate the currents stay on the inside surface of a conductor with significant thickness, especially near the drive end of the loop. This implies that the optimum conductor may actually be a half-tube. Where current bunching pushes currents to the edges, but the induction action in the antenna pulls the currents torwards the smallest radius section of the tube. The result being an even coduction across the surface of the half-round conductor.

Hi Richard,

This is a symptom of the 7 MHz length of your loop is borderline magnetic/borderline folded dipole. The two modes combine and change the impedance of the antenna. You will also note that its omnidirectional on 7 MHz, or nearly so. 4.5 meters diameter results in a 14.2 meter loop length, which is .35 lamda on the 40 meter band.

I have the same action on my 1 1/4 meter diameter loop antenna, where its a nice mag-loop at 7 MHz, but its an omin mag/folded loop at 14 MHz.

I happened to have tuned my coupling loop for best match at 14 MHz, and then its about 2:1 at the low end of 40, which I then use a match box to fix.

You can address this by motorizing your coupling loop , so that you can squash it down at the high frequencies, and return it to circular at the low frequenies (or visa versa). Another possibility is two coupling loops, and just switch between the too. Make sure the loops have good RF high voltage capability. Because the unused loop will see on the order of twice your drive voltage to the coupling loop in use.

The problem with this approach is that high efficiency necessarily
results in very narrow bandwidth and very high Q (ie high voltages
across the gap). At some point, it becomes impractical as an antenna.

Right

> true high frequency analysis, its just not clear how wide the strip has
> to be before the current bunching increases the resistance by what

A tubular conductor uniquely has no edges for current to bunch up
on, and due to circular symmetry, the current is forced to be uniform.
Any non closed cross section will have current bunching.

> percentage over the predicted surface area resistance. Indeed, what
> modelling I have done on this issue tends to indicate the currents stay

What tool are you using to model? I did a bunch of measurements on
loops and found that the Q goes up as the conductor thickness increases,
but only to a point of diminishing returns. After that, you can't
get a higher Q no matter how thick the conductor. (This was for a
solid wire conductor). This maximum Q was only several hundred,
and could not be explained by radiation resistance. I hypothesized
that the currents were being bunched up by the magnetic field and
were not fully utilizing the conductor.

That's interesting; two opposing effects. Hard to say which one "wins"

7489. Feeding A Magnetic TX Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-05-16 15:21:11 UTC
From: toddroberts2001@aol.com
Topic: 7489 Message: 7489

Hi All,
I am wondering if anyone has tried locating the feed loop
or Gamma match next to the tuning capacitor and if
they had success with this arrangement?

This would simplify tuning/matching the loop and
simplify construction a bit if the tuning cap and
feedpoint could be located close together, especially for a
larger size loop. This is compared to the normal method
of locating the tuning capacitor at the opposite end of the loop
away from the feedpoint. This requires locating the tuning capacitor at
the highest point of the loop and complicates the mechanical
construction especially for a larger circumference loop like a 70
ft circumference loop for 80 meters.

I know it will unbalance the loop if the gamma
match ground point is next to the tuning capacitor
but I don't see any reason why it wouldn't work.

Unbalancing the loop should mainly effect the
sharpness of the null direction but for transmitting
most people want the antenna to be more omnidirectional.

I plan to experiment with this feed method over the next
few months and will report on how it works for me. My test
loop will be a square loop 30-40ft circumference for 40
meters only for highest efficiency.

Hiya
Yes that would definitely explain the action, I did reduce the circumference a bit , I removed about a foot which on topband gave my all but the to 10 KHz, but the Q is very high, the bandwidth is only just wide enough for SSB.
If they ever give us 5 MHz as a permanent addition, at the moment you have to apply to use it.
To get the best coupling the coupling loop[is already squashed down to more like a folded dipole.

I've tried comparisons between the loop and the shortened 40 mtr dipole, there's not much in it, so maybe best to leave it for now,
The next motorising project must be the ATU, that could then be put outside.
Might even be able to use a 2.3 GHz control link, but Id have to turn it off when I use 2.3 GHz, 120W to a small dish!

<<SNIP>>

You may want to consider an alternative balanced feed method that I devised after listening to many people complain about the various earlier transmitting loop feed methods:

http://www.home.earthlink.net/~christrask/Paper012.html

It simplifies the mechanics, does away with the expensive vacuum variable capacitor, and does not compromise the balance of the feed.

Yes, and maybe ... hi hi. I have fed a small loop (about 4' in dia ... 12.5' in circumference) with a short length of parallel feed line and a balanced antenna tuner (the tuner tunes the loop and matches the feed line at the same time) and used it from approx 5 - 15 mhz. The project started as a tuned loop for SW reception. The feed line was about 8' long ... from the loop to the balcony window. It was an excellent receiving loop which had sharp nulls ... good for nulling local RFI. The loop material started with RG58 (tied together as a single conductor). Out of curiosity I tried feeding it with a 20m QRP radio and lo and behold I managed a few contacts. I then upgraded the loop to 3/8" solid copper tubing .... es upgraded the feed line from TV twin lead to heavy duty 450 ladder line .... and I could make regular 20m contacts with my QRP radio.

That is as far as I got with the experiment. However I think the next step would be to upgrade the antenna tuner with heavier duty capacitors and to substitute home brew rigid feed line for the 450 ohm ladder line .... and make the loop itself (same diameter) out of 1/2" copper tubing. I believe I could feed higher power to the loop (up to 100 watts). I could see the loop mounted with the base about 8' up on a rotatable pole with the tuner at the base and the rigid feed line mounted along the length of the pole.

the antenna tuner was a simple link coupled L-match (often called a Z-match tuner). Tuning the loop and matching the 50 ohm load of the radio was a snap.

Now I have seen other experiments with larger loops (although less than 1 wavelength) where the loop is tuned at the base and the feed point is moved off-center. The feed point impedance changes the further you move it off center. the experimenter moved the feed point to a place that was mechanically convenient and presented an impedance that could be easily fed with a fixed RF transformer. The impedance would of course change as you changed bands .... which would make me think that if the plan was to use the loop for multi-bands it would make sense to couple the feed point with an antenna tuner to accomplish both tasks ... tuning and coupling with what would then be a combined tuner/matcher hi hi.

The smaller the loop the more robust the tuning components must be .... as well as the construction of the loop itself.

Hi Andrew,

Almost except he has connections at both sides of the loop .... feed line
on one side and tuning capacitor on the other. Keep the antenna tuner
(Z-match) .... keep the feed line (only 8' long ladder line) .... remove
the tuning capacitor and replace with the end of the ladder line. There is
only 1 connection to the loop. The z-match both tunes the loop and couples
it to the radio. In fact, the loop could sit on the same table as the
tuner and radio which would eliminate the feed line altogether. I would
need to construct a new unit with more robust components. The unit I used
could handle 5 watts .... anymore and I am sure the capacitors would arc.

The reason I mentioned the feed line and the 8ft pole is I am sure I
wouldn't like the idea of sitting next to the loop with 100 w of RF hi
hi. I'm not fussy about 2 adjustments (coupling and tuning) in two
different locations. As I mentioned I stumbled on the single point
arrangement in a receiving application and it seems to have application for
transmission as well. In the most common arrangement you need to run over
to the loop every time you want to touch up the loop tuning or use more
complicated remote tuning.

Maybe I will experiment with a robust system this summer ... the loop would
remain permanently on the deck with a short heavy duty feed line to the
operating position. I would need to weather proof the ant/loop tuner.

Rick:

Check out Stormwise dot com. They have thick ferrite rods that will be very useful for making a MW ferrite antenna. I used a 13.5" x1.25" rod passively tuned with a variable capacitor, and used a separate 3-turn winding for a hi-Z [~500 ohm] input into my R75. Works very well, VERY quiet. They also sell tuned units integrated to permit sending to radio direct, maybe another option?

Basically, parallel tune the rod to get the resonance. Abotu 45-50 turns on the 125u rods is around 270-300uH, ideal for a small varible in the 270-365pF [max range].

I don't have a specific design for you, but I have some experimental results using cheap and available long form ferrite beads, assembled into a rod, in 3 materials. The most generic medium frequency material (Steward type 28) performed very well (based on the Q of various coils) at 500kHz. I also experimented with the effect on the Q of introducing small gaps between the stacked beads.

The reports are in the Popelish folder of the files section of the ferriterodantennaexperimenters yahoo discussion group with file names of:
Experiment_Q_vs_F_vs_GAPS_5z.pdf
Experiment_Q_vs_F_vs_GAP_Distribution.pdf

Perhaps this work will give you some leads.

Hi, I've post a video on my blog of dxing using my experimental ferrite loop antenna.

I's possible to see the results of signal increase hearing FIRS Falklands (1,500 miles away).

I have made several experimentation and recorded some interesting features, like nulling, and I will be continuously posting the videos and comments on my blog.

My first post at :

thats quite a loop stick you got there (nice fat one!) i have a "Select-A-Tenna" for an indoors AM broadcast band antenna that works nicely and has a tuning capacitor of some sort, i have never opened it as it seems to be a sealed unit so i have no idea what is inside the Select-A-Tenna,

i enjoy turning the AM broadcast band at night i just wish there was not dozens of stations all playing the same program (CoastToCoastAM) that show is for loonys, a person has to be crazy to believe the drivel they broadcast on coasttocoastam, but once in a while i find a good station, 650 WSM out of Nashville Tennessee is a good one

Hi Lars,

A 120m loop (horizontally oriented I assume) will make an excellent antenna on all bands 160m to 10m ... higher the better. It is impossible to predict the impedance it will present at whatever frequencies you are planning to use. However it is safe to say their will be considerable impedance range to deal with. You already mentioned ladder line (the characteristic impedance of the ladder line is of no consequence ... e.g. 300 and 450 ohm is common .. home made 600 ohm line even better) .... you also don't need to have the same line all the way. You can start with 300 ohm line then connect to 450 ohm line ... and it won't matter a whit .... but choose the best quality that is practical for you. The loop is a balanced load and your radio is an unbalanced RF power source. A conversion from balanced to unbalanced needs to take place somewhere between the antenna and the radio. The best scenario is to bring the ladder line as close to the radio as possible and to terminate it at a balanced antenna tuner. (it is a myth that parallel feed line radiates). Bringing proper balanced line into the shack is less troublesome than coax that is not properly terminated in whatever balanced to unbalanced device you use.

Most commercially manufactured antenna tuners are designed to match an unbalanced load to an unbalanced source (the radio). Most of these tuners will have a built-in balun (a transmission line transformer) at the antenna end of the tuner to accommodate balanced feed lines (usually as an after-thought). This is the best place for it if you are going to use a balun. You should use as robust a balun as possible as the impedances it will face will range considerably from the impedance range of 50 to 200 ohms that it likes. Once the impedance ranges farther .... with added complexity of either capacitive or inductive reactance it plays havoc with ferrite wound baluns.

The ideal would be to use an antenna tuner designed particularly for balanced feed line. They were common in early times ... then all but disappeared ... but seem to be coming back. Another ideal solution would

be to put an external automatic antenna tuner right at the feed point ... and then use high quality coax feed line all the way to the shack (SGC makes such tuners).

I would avoid RG58 if possible and go to RG8 or RG213 .... that is if you insist on putting the balun some distance away from the shack.

Hi Lars. I would echo most of what Jim says here. I had up a 120m loop last fall. Im not sure if I tried to tune 160m or not. If I did, it didn't work with my tuner. Worked 80m, 40m and 20m really good. Never spent time on the other bands, but should tune up to 10m or even 6m fine. I wound up shortening it to 80m. The main difference is in the pattern. The 120m had more lobes on 20m with some pretty good gain, but also more deep nulls. The 80m loop has almost as much gain on 20m but a bit more coverage. As far as a balun goes, I feed the loop with 450ohm line. right after entry to the shack I have a homebrew 4:1, than to the coax inptu of my cheap little tuner. I don't use the built in. But I guess the best setup, which I may try and mod/rebuild my tuner, is the balanced line coming straight from the matching network, with a 1:1 50ohm balun on the transmitter side. Good luck with yours!

7510. 2M/70cm/HF transceiver loop antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-05-20 04:19:35 UTC
From: Bill McGraw
Topic: 7510 Message: 7510

Group,

I need some advice and have lots of questions.

I'm a new Technician, will take the General this summer. I'm 65 and have been DX'ing for 50 years, made and still make crystal sets, small and large horizontal and vertical loops for inside my office for small AM radios, a RS DX 398, and an OCF vertical for a scanner. I have a borrowed 2M/70cm dual band radio and was given an MFJ 1522 antenna mounted on a 10' PVC mast.

I understand the compromise with 2M/70cm/HF radios but I want to have the least equipment possible for my office/shack, already cramped space and would want to be able go mobile with 12V DC power or to camp sites. Some of these radios--Kenwood, Yaesu and ICOM--have built-in ATU's and I'd want that. A power supply and 120V AC would be useful if the radio would work on both. I have 2 12V batteries I use for other appliances and CB radios and could use them for camping.

What would be the minimum loop antenna for the HF radio, 160-10M, shape, orientation--horizontal easiest, minimum height and any proper coax? What loop could I use for mobile or camping?

I am getting dense in my early disabled retirement some 18 years ago, so go easy on terminology and connections. I have plenty of TV coax and would consider using it for a loop.

Hi rich3x,

I think you mean 1/4 " shaft.

I would not worry about the shaft size too much. You can always adapt with parts from SDP/SI - google it! They do small orders no problem.

From: Joe
Topic: 162 Message: 7513

Hi All,

After much time spent thinking about loop antennas I finally got to build one.

The loop I built is a 36 inch diameter loop of 3/8 inch soft copper tubing. I am feeding it with a wire loop. (not a faraday shield).
I also built a stand which holds the bottom of the loop about 4 feet off the floor. The cap I used is a two gang cap with the gangs connected in series so I do not go thru any wiper connections.

I placed the feed loop at the top so I could get to the cap better for tuning.

The results of this loop and the cap I used are:

Tunes from 20 meters to 10 meters with a SWR on 20 meters of 1.1:1 and it goes up until I get to 10 meters where it is 1.5:1. I have not been able to get the SWR flat across this frequency spread.

So far I have not made any contacts with it. On receive it seems to be about 1 S unit below my attic antennas. (I live in a restricted area and cannot have outside antennas.)

With the cap I am using I cannot use output power over 20 watts. I guess this will be my QRP antenna to use with my FT-817. I hope to use it portable in local parks. The stand I built is of Schedule 40 PVC pipe. I built it so I can take it apart in a few sections to make it easy for transporting.

I would be interested in hearing any comments from other users of this type of antenna.

With our Sun behaving like a crazy guy, MW propagation is very strange nowadays in my region. I used to listen to Saudi Arabia (1512kHz), France Info (1557 kHz) and others using just the ferrite loop antenna.

I have tested another loop, which is supposed to have much more gain and no transoceanic DX, just South America.

You can see the video of this one, nulling a local power station and bringing Argentina, Paraguay and Uruguay:

Hi John, as a matter of fact, my main objective here is to share and most important to me, is to learn about loop antennas.

Next try I will change the coupling method. Instead of magnetically coupling I will directly connect the loop into the receiver.

I wonder if a coupling coil, with 2 or 3 turns will be suffice to couple into the low impedance input of the receiver (50 Ohms).

In theory, at least, it's supposed to use another variable capacitor to tune this coupling loop too, but capacitance should be very high. An the other way, the higher the number of turns of this coupling coil, less capacitance needed, but it may be an issue to the main tuned loop.

I think of using a low capacity coaxial cable ☐ like RGC58, to connect this coupling loop into the Icom.

Any idea about it?

Regards
Sarmento

Sarmento:

Before discussion alternate coupling methods, I have a few
questions about the designs described in this web page:

http://www.sarmento.eng.br/Loop_Ferrite_Rod_Antenna.htm

You spend a lot of effort talking about rod arrangements and
their lines of contact and packing density. But without
quantitative comparisons, I am having trouble visualizing
how these differences matter. I tend to think more about
the physical coupling between the external RF fields and the
rods and coils.

Based on this point of view, I suspect that you might well
see almost identical results with the inner layer of rods
completely removed and replaced with spacers. I picture the
effects of the rods as a magnetic sort of short circuit for
the magnetic component of the EM waves, gathering flux over
the exposed rod surfaces near their ends and passing it all
through the center section. The inner layer or rods, having

much less surface exposed to these external fields (only their ends) might not be utilized as effectively as the outer layer.

Also, from this point of view, there should be more RF flux near the center of the rod than near the ends, but I see your drawings showing the coil near one end, rather than being in the center. But I see no reason given for this choice.

From the photos, it also appears that you place your tuning capacitors right against the end of the rod bundle, where the gathered external flux would be most concentrated. This would cause the flux to go around or to penetrate the metal parts of the capacitor, while producing eddy current losses and signal reduction from those diversions and losses.

I would be happy to read any reactions you might have to these thoughts.

Hi Sarmento,

At what time (GMT) you did the listenings you mentioned? I?m trying to
listen MW transoceanic (1512kHz, 1557kHz and so on) here in Florianopolis
for a while, without success.
Any other transoceanic listenings you could mention, so I could try them
here?

Hi Vlad

I haven't tested yet using my long time sleeping mini-bog during gray line, but some stations should be easy to catch like :

684 kHz, Spain
1548 kHz, Moscow/Kuwait
1620 kHz, Caribbean region
1503 kHz, Taiwan (during gray line)
1476 kHz, Dubai
(some of this stations have already been logged in Lorena/São Paulo several times)

Hi Alex

I bought the ferrite rods from a Brazilian industry called Sontag. They export several models (specially for MW and SW frequency ranges).

The difference of this antenna comparing to the classical bazooka is the internal disposal of the rods and the rods specification.

I'll take same pics to show it inside and try to scan the datasheet of the rods I have used.

Hi John

This weekend I will write a briefing about it. Your exposure is extremely relevant and was the basis of my research.

I have tested two distinct ferrite sticks, one appropriate for lower frequencies and higher frequencies, and I have also tried to use powder. I had access to the raw material (it's another story) during its production.

And there were big differences of performance.

The variable capacitor is located 10 cm distant from the bundle of ferrites that's why the antenna is so big, I mean, due to the considerations you note, it's ok.

I will post more pics of the assembly to write more about it.

Regards
Sarmento

7526. Help making the most out of my new purchase

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-05-28 05:43:36 UTC
From: corbintechboy
Topic: 7526 Message: 7526

Hello,

New here and have a few questions.

I just ordered what will be my first "real radio" after years in the radio hobby. I ordered the Yaesu FRG-100 and very excited about my purchase. Naturally after being in the Shortwave hobby for many years I have played with many different types of wires and such to try and get the best signals on the little radios I have had.

With this purchase, I want to match this radio with the best antenna solution that fits into the constraints I have here at the house. I have been looking at some different loops across the net and have done some reading as to what I would like to do. The amount of space I have here is a real issue and a ground is no way practical at all. The radio will be on the second floor of an older home with no pipes in sight and no way to put anything out a window, in front of a window is fine for my situation here.

Now the questions:

I will be doing a lot of utility decoding and whatnot with the radio as well as some broadcast listening and have no real "target" as to where in the bands I want this radio to shine. I have been reading about the "Magnet loop" and this really appeals to me for the local noise canceling features. What is the smallest I can get away with and not sacrifice the amount of signal I recieve?

Another thing I was looking at is just making an all out loop and would like to know if I were able to wrap a wire like I think 462 inches around a loop for the 6.0Mhz area would all the frequencies above the 6.0Mhz be able to use an antenna tuner to make the loop efficient up to around 15.0Mhz?

I have no electronic skills and making any kind of soldered type board is out of the question, do I need to?

Space is about my main constraint here, dont have much.

Thanks in advance for the help!

Hello again,

I now realize after doing more reading that my post is very misinformed.

I was under the impression that I needed to make the wire in a loop a 1/4 wave in order for it to work if I were to do an all out loop (if that makes sense). I did more research and have learned this is not the case.

I got on the radio last night at 0000 UTC and noticed that the setup I have here is not much good on the SW bands. I did indeed pick up some stations but the noise floor was very high (S6-8). On MW the wire wrapped around my room fared much better and I was able to do some good MW DX. In a sense what I have here is a big loop around the ceiling.

I still have questions. A lot of the info I find about magnetic loops has to do with transmitting, something I won't be doing. Do the same rules apply?

Also wondering about the size, I read that I can use 1/10 wavelength and I am really lost as to how to calculate that. I don't understand the size.

I also am wondering about the variable capacitor, does this have to be attached to the loop or can I move it closer to my station? The way I have the radio here the radio will be on one side of the room and the loop on another. If I can attach the capacitor to the coax it will be much easier.

In front of the window I have about 3.5 feet in width I can play with, if I were to move the loop to an inside wall I got about 5 food in width at that point. I live in a vinyl sided wood house so the inside wall could even work.

Thinking about the target frequencies, I think my interest lies at around 4Mhz up to around 15Mhz there bouts. Could this be done in the space constraints?

Been on ebay looking at capacitors and there are some really nice ones to be had. Should I get one with only one tuning set of fins? Or should I get one with three?

Hope I make a little more sense this time around.

Hi,

almost any length of wire will "work" whether configured as a loop or as a straight piece with the feed point located in the middle (dipole or doublet). Both configurations loop and dipole have a common characteristic in that they are considered "balanced". By that it is meant that the antenna element is complete and does not require a reference to ground, earth, counterpoise, or whatever you want to call it ... in order for RF currents to flow through the feed line to the radio.

When you speak of 1/4, 1/2, or 1 wavelength etc.. you are talking about the electrical length of the element at a particular frequency and resonance. I just so happens that an element that is 1/2 wavelength at some particular frequency and is arranged as a dipole represents some desirable attributes .... e.g. presents approximately 50 ohms impedance (with no complicated inductive or capacitive reactance). If you increase the length to 1 full wavelength and configure it into a loop it presents approximately 100 ohms.

The information above only makes sense for frequencies in the HF range of 3.5 to 30 mhz. Frequencies lower than 2-3 mhz become too large to be practical in terms of resonant lengths.

Generally speaking NO. The most critical aspect in constructing a small loop (generally one that is considerably smaller than 1/4 wavelength in circumference) is to make the element, tuning, and coupling components

robust enough to withstand high RF currents and voltages.

>Also wondering about the size, I read that I can use 1/10 wavelength and I
>am really lost as to how to calculate that. I don't understand the size.

As mentioned in the first comments the smallest (naturally resonant) loop antenna is considered the 1 full wavelength. The rule of thumb formula for calculating this length is 1005/Frequency. So a naturally resonant loop for 14 mhz would be 1005/14 = 72' 8" It has certain characteristics in terms of input impedance and radiation pattern. A loop that is 1/10 wavelength would be only a little more than 7ft in circumference and it needs to be "tuned" in order to become resonant (to make up for the shortened length) and has much different feed and radiation characteristics.

When the loop is large ... it will work well even if it is not resonant ... as in the case of the loop around the room. If it is small (in the 1/10 WL range) it generally must be tuned in order to perform adequately. (there are exceptions .... eg. providing much additional RF amplification).

>I also am wondering about the variable capacitor, does this have to be

Yes, the capacitor can be located at a distance from the loop

The portion of the loop opposite the capacitor is the only real
place to get a low impedance feed point which the gamma match
requires. You would have difficulty feeding the loop anywhere
around the capacitor because of the very high voltages there.

Believe me, it would greatly simplify the construction of the
magloops if the feedpoint and capacitor could be colocated -- thats
why you never see it in magloop articles.

I'm in the process of building a loop now. Due to medical reasons
I had to sell my house and move into a residence where I could get
nursing assistance. I have a nice patio, and that's where the loop
is going to sit. I just picked up a Yaesu ND-817 and am looking

to get back on the air again. I'll propably build two loops in order to cover 80 thru 10M with a reasonably degree of efficiency.

With 50+ years of ham radio using twin lead (300Ohm Twin Lead)
I've run across metal pipes, under metal doors, over filing
cabinets, under metal window screens, and almost anywhere I had
to to get a line out of doors. Without any consideration of
do's and dont's by technical gurus, kind of like the bumblebee
who the gurus say cannot fly but flies, I have enjoyed countless
years of fun using this feeder. I've never run more than a hundred watts or so, and never
worried about distance from other metal
surfaces. In a pinch I've even used zip cord!
Get the line out any way you can and get on the air. Then make
changes if you feel you aren't getting out -- but I think you'll
be pleased. I sure was!

That's quite interesting and is what I observed when I tried to feed a loop next to the tuning capacitor; the gamma feed needed to be increased to a size much larger than typical and I gave up when I could not get the SWR below 3:1 with a large gamma section on a 1/4 circumference loop.

Hi Irv,

It is not really difficult to couple to the loop at the tuning capacitor. The circuitry is simple ... the problem is as you say ... dealing with the high RF voltages. It also relates to the amount of power you run. If you run QRP no problem.

>Believe me, it would greatly simplify the construction of the
>magloops if the feedpoint and capacitor could be colocated -- thats
>why you never see it in magloop articles.

The reason you don't see it done is that it requires non-traditional methods.

MFJ made several versions of a Mag Loop Tuner that operated in this fashion. Simply connect the loop to the 2 stand-off insulators. the tuner acted as the base as well as the tuner and it could sit on the table next to the rig. I didn't particular like the idea of the mag loop sitting a couple of feet away from me ... even though I was only operating 10 watts output.

I extended the distance. The version I built separated the loop from the tuning capacitor/coupling unit by about 8 feet using home brew parallel feed line.The loop was about 3 ft in diameter and I ran 10 watts output (I used a Kenwood TS-50 running at the low power output setting) no

problem. it worked just as well as the same loop fed in the more traditional way at the low impedance side. If I fed the same loop at the low impedance side I could easily run 50 watts .... but then I had the inconvenience of not being able to tune the loop and adjust coupling from the operating position. By the way ... the loop was fastened to the balcony railing and the tuner/coupler was just inside the window to the apartment. Both loop arrangements had the same efficiency (e.g. output). The difference was that feeding the high impedance point dramatically lowers the 'destruction' point hi hi.

It is not a matter of will it work. It works! ... It is just not easily done with traditional components. Modern day Amateurs love coax .... and coax is incompatible with high impedance feed. If Mag loops were popular back in the 1930's I am sure that is how it would have been done (that is tuning and feed at the same point).

Hi Irv,

you're absolutely right. 300 ohm twin-lead made it's appearance in the 50's with the advent of TV (at least in my neck of the woods) and it became the miracle feed line. It handles 100 watts to non-resonant multi-band doublets no problem .... if the particular length at a particular band causes a bit of a matching problem ... simply add 10 to 15 feet (rolled up on the floor) and it usually does the trick. If you use it as both the feed line and antenna in a resonant folded dipole you can put the power up to about 500 watts ... I personally have run such an arrangement with 300 watts full Amplitued modulation.

It is non fussy ... lets face it ... it was originally designed to be used with VHF .... so it is guaranteed to be effective at HF.

>why you never see it in magloop articles.

The reason you don't see it done is that it requires non-traditional
methods.

MFJ made several versions of a Mag Loop Tuner that operated in this
fashion. Simply connect the loop to the 2 stand-off insulators. the tuner
acted as the base as well as the tuner and it could sit on the table next
to the rig. I didn't particular like the idea of the mag loop sitting a
couple of feet away from me ... even though I was only operating 10 watts
output.

Hi All,
Thanks for the many ideas and suggestions on trying to feed a
magloop next to the tuning capacitor. I had forgotten about the MFJ
loop tuners that use a capacitive match right next to the tuning capacitor.

It looks like the Gamma Match is not really suited to feed a loop with
at a high-impedance point like right near the tuning cap, but works well at
the
low impedance point opposite the loop tuning cap. Plus by its nature one
side
of the Gamma Match is grounded. That would upset the balance of the loop

if placed right next to the loop tuning cap.

About 15 years ago I did successfully feed a balanced, ungrounded loop next to the tuning capacitor once with an unusual arrangement. I was using a QRP transmitter with a tuned tank coil and inductively coupled the tank coil into a corner of a magloop right next to the tuning capacitor. I made the tank coil out of about 3 turns of wire about 1 ft in diameter feeding a loop 10 ft square or 40 ft circumference. This was in the Medfer band about 1645KHz. The tank coil was resonated with its own tuning capacitor. Then I varied the spacing to the loop for best loading. So I was basically coupling one tuned coil into another larger tuned coil (the loop). The tuned tank coil of the Mosfet final was not a real high impedance like you would find in a tube final but I would guess was somewhere in the range of 250-300 ohms.

This makes me think that perhaps stepping up the 50 ohm output of common coax feedline with a 1:2 or 1:3 ratio transformer to start with and feeding that into either a larger-size single-turn feed loop or perhaps a multi-turn feedloop would give a better match at the higher-impedance feedpoint next to the loop tuning capacitor? Then keep experimenting with the step-up turns ratio and size of the feedloop plus spacing to see if best match can be found?

I will report back on this if I can get any success with this method over the summer.

I'm surprised that no one has mentioned that on electricaly small loops (< .10 lamda) there is no low impedance point. So essentially you can put the matching network where ever it is practicle.

Hi, all. I live in a HOA restricted community. As such, I purchased a MFJ 1786 loop antenna. This purchase was based on what I read on the net and reviews on eham. The antenna is on a 5ft pvc mast held by a umbrella stand. It sits on a deck that is approximately 9' above ground level. I have had some difficulty tuning the loop but am improving. My concern is that reception is poor on all bands(30-10 meters). Contacts are practically nil. I do have a fellow ham that is approximately 2-3 miles from me. He can copy me and I,he. That it is it. I do not know what antenna system he is using. My experience with this antenna does not come close to those who have reported on this antenna.

Is there anyone here who has experience with this antenna who could advise me as to how I might be able to get this antenna to perform for me before I decide to move on and try another stealth system.

Thank you.

Is the loop mounted horizontally or vertically? If it is horizontal at 9ft above the ground your losses will approach 30db on the lower frequencies. A magnetic loop is to be mounted vertically when low to the ground.

If you mount it in the attic, say 20ft or more above ground, you can get away with horizontally mounting it then. I had an AEA Isoloop mounted horizontally at 25ft above ground in my attic and it worked great on stateside and DX.

Overall, the loop will be MUCH quieter than a dipole, even when tuned to resonance.

Are you getting near 1:1 SWR when the loop is tuned? If your rig has an autotuner built it, turn it off, you cannot use any tuner other than that which came with the loop.

Hi Todd,

I am supprised that nobody has mentioned the british ham that has patented this idea. I first learned of him, and his website on this list actually.
http://www.g0cwt.co.uk/magloops/new_page_5.htm

Yes, it does simplify the consturction, as the coupling and tuning can all be put in one box, ala the mentioned MFJ product. Also, check out Ka8zty's pictures.

I did not go that way with my loop, however. I have lots of nearby conducted interferance soures in the vacinity of my antenna. To help reduce electrostatic coupling from these sources, I wanted the shielded loop feed at the magenetic end of the antenna. A dipole here picks up so much of this noise, that its not usable. The Mag loop is much better, can be moved around and oriented for the best signal and signal quality, unlike the Dipole.

I just ran across this forum and thought you all would enjoy the pics of my 40m magloop I posted under my callsign. I used 1-5/8" copper pipe in a hexagon shape with a loop diameter of approx 6.3 feet. It's fed with a gamma match, and the capacitor is a 5KV vacuum variable. I have it mounted with the feedpoint at about 7.5 feet above ground vertically polorized. It will outperform my inverted V at 35 feet under some conditions.

Specs @ 100w:
Loop Circumference 21.00 feet
Conductor Diameter 1.63 inches
Frequency 7.20 mHz
Bandwidth 9.6 kHz
Capacitor Value 95.1 pF
Capacitor Voltage 3.9 kV
Conductor Wavelength 0.162 lamda
Efficiency 74.4 %
Inductance 4.456 µH
Inductive Reactance 201.6 ohms
Loop Area 33.3 feet²
Loop Diameter 6.3 feet
Loop Q Value 746.3 Qres
Radiation Resistance 0.101 ohms
Resistance Loss 0.035 ohms

Hi, Andrew, thank you for your response. I am sorry that I
neglected to state that the
antenna is vertically polarized. The autotuner is off. The
feedpoint is approximately 19'
above ground level. SWR on most frequencies is 1:1 or close.
Several frequencies
2:1

Nice job! How do you tune the cap?

What is the silver circular object below the cap?

Have you tried to measure the actual Q to compare to theoretical?

I leave the loop tuned to 7.195 and use my inverted V for the rest of the band. The objects below the cap are a 6:1 reduction gear mounted on standoffs, a plastic insulator, and a knurled tuning knob. Without the reduction gear the tuning would be way too sharp. I haven't measured the Q.

This past week the higher bands have been pretty dead except for some sporadic activity. Keep an eye on:
http://www.n3kl.org/sun/noaa.html

With geomagnetic storms around it will stomp HF activities a times. I am listening to 20M right now on a sloping Par EndFedz 1/2w antenna and it is very quiet across the band at noon Saturday.

It sounds like you are set up correctly, I'd give it a week or so and keep trying at various times. 30M in the evening may open up if things remain settled.

It's hard to judge an antenna when band conditions are less than optimal.

Mark,

That is an example of a textbook perfect magnetic loop, very nicely done!

Lately I have been able to use a hidden inv. vee on 40M but I still use the loop for receive since it is much much quieter with all that summer static on the bands. While everyone else on frequency complains about S8-9 crashes I enjoy the same signal strength on receive but the static is down near S1-3.

Thanks for sharing that with us!

Thanks Andrew,
I have to give credit to Tom/W5QI for putting the idea in my head and Dale/KD7AKV for his plumbing skills during the construction. It's a very expensive antenna to buld, but a fun project that produces pretty good results IMHO.

I looked in the links and didn't see this page posted. Has anyone tried this design for a 10m loop?

Link <http://www.antennex.com/hws/ws0902/hardline.html>

I have some 7/8" hardline and may give it a try.

I got the gear reduction drive motors for mine from Electronics Goldmine. Here's my writeup for that design, which has photos showing the mechanics:

Mine is just a reduction gear for manual tuning, I built the loop optimized for 7.2mHz. You guys that build the motor drives to tune the cap are hardcore. This antenna really started out as just an experiment, but I'm not very active anymore and it is still tuned to my favorite freq and works flawlessly every time I need it even after about 4 years out in the elements.

Mark,

Yes, I've used 7/8" aluminum hardline to make that very loop for 40M. I will say it will make a very small resonant magnetic loop. A 10ft length of hardline resonated below 40M around 6.3MHz and I had to trim several inches to get it up on 40M (I forget the actual final length). The tuning cap made by wrapping the wire around one end of the loop works but at QRP levels only. Using anything over 20w seemed to cause a drift in the frequency likely due to heat. By using a short section of RG8 coax as a tuning stub it stabilized the drift and I was able to run 50+ watts into it. At that frequency the loop will be quite inefficient but it will work.

When you say 10m are you referring to 10M or the length? At 10M the loop will be very small. You would be better off using a small feed loop with a 30inch diameter hardline loop. I made a few very nice fixed frequency mag loops with hardline and they are installed in the attic horizontally.

One thing I'd like to add regarding my 40m loop. Even though the cap is rated at 5kv, it is tuned at the low end of it's capacatance limit and I have given it 800w with my old Henry 2K which pushes the cap up to about 11kv without issues so far.

7561. 40 Metre Delta Loop on 80 metres Severe RF on audio

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-06-06 20:29:51 UTC
From: david_oxon
Topic: 7561 Message: 7561

I have a 40 metre full wave delta loop antenna. The apex of the triangle is 11 metres high and the base is 2 metres high. I feed it approx 2 metres from one of the base corners on the upward sloping side of the antenna with 50 ohm coax via a 4:1 balun. My rig is the Yaesu FT-950. The antenna works very well on 40, 20 & 10 metres. However, when I try to use it on 80 metres I get severe RF on my audio. I have tried the following all to no avail:
☐ 6 turns of the coax about 150 mm in diameter close to the balun.

☐ Using a large loading coil in the middle of the base of the antenna with several taps to try to resonate the antenna on 80 metres.

☐ Using my Yaesu FC-301 10 to 160 metre selectable ATU.

Any suggestions please?

Hello David. It is highly unlikely that the 4:1 balun is seeing a suitable impedance on it's output side. Ideally it is looking for 200 ohms to match in the 4:1 ratio. The quick solution could be to break the loop at about 63 feet from the feedpoint and use it with the other section as counterpoise. You would then close the break to resume ops on 40 -10M. The balun is not wanted on 80M.

H Chris,

I enjoyed your article, Transmitting Loop for 40M Band, and am thinking about changing my loop to reflect your design. I sent you a few questions about your article. The main ones were:

In Figure 1 you show the measured resistance of a 1.5m loop. I'm not sure what you are illustrating. The applicable text says the measured impedance, the Figure says resistance. 12ohms at 11MHz seems very high for the resistance. Is the graph showing magnitude of impedance?
Did you graph the impedance of the lumped element model, if so could you send a copy?
How did you guarantee a loop resistance of 3.125 ohms? Or was near enough good enough?
Your capacitor is a dual 50pF, 800V. What is the relationship between the 50pF and the 250pF or so that would otherwise be required to resonate the loop at 7MHz, ie how did you determine 50pF? Also, how does the required voltage change. ie I need 3-4kV at 100W if I use a traditional approach to resonate the loop. What voltage does the capacitor in your design need to be?

Cheers
Mike, VK1OO

The chart is showing resistance, the real part of the impedance. The 12 ohms at 11MHz is not at all unrealistic as you're approaching the first parallel resonance of the loop.

>
> Did you graph the impedance of the lumped element model, if so could you
> send a copy?

I may have, but I have no idea where it is at the moment. That was from another project where I was trying to wideband match a similar loop. That turned into a dead end.

>
> How did you guarantee a loop resistance of 3.125 ohms? Or was near

Using the same diameter of flexible copper tubing it becomes repeatable.

>

> capacitor in your design need to be?
>

It only needs to be a few hundred volts as it is at a lower voltage and higher current point in the network in relation to the 50-ohm feedline. In this case, the variable capacitors will see a voltage a quarter that of the feedline voltage. The 50pF was derived by first using a dual 365-pf and measuring the capacitance needed to cover the desired bandwidth. Then I rummaged around in my stock and came up with a pair of higher voltage dual variables. The 50pF dual combined with the padding capacitor suited my

desired goal.

The need for the excessive voltage for the capacitor in the traditional approach is that it is placed at the point of the loop where the voltage gradient is highest. The lowest voltage gradient is at the feedpoint, but a dual variable for that approach would present mechanical difficulties. My design started from that point and then I moved the capacitor(s) further away from the feedpoint until it looked practical. Then it came down to how to design the tansformers to minimize the losses.

Bob, you pose an interesting question especially at VHF where this sort of thing is usually done with beams. I suppose I should ask what exactly is your objective with such an array. Have you modeled this in any way?? I wonder if three bays of two vertically stacked Big Wheels (off each side of your tower) wouldn't be more manageable and just as good though that would mean 6 and not 8 antennas. I really need to know your overall objective that call for eight antennas.

Hi
Yes this is a strange thing to do on 2mtrs, especially now with all the crap
and QRM. You will be at a big disadvantage with an omni directional antenna,
unless you are going to use it for a beacon.
A 60' tower deserves a decent size antenna, something like a box of four
boomers. QRM is such a problem that I'm reducing my array slightly so that I
can bay all the antennas with a clean pattern.
Just my thoughts

Loop antennas can be characterized as a shorted length of parallel-wire transmission line. The terminal impedance looks like an open when the equivalent length is a quarter wavelength long (first parallel resonance) and as a short when it is a half wavelength long (first anti-resonance). This then repeats itself for every odd-integral (parallel resonance) and even-integral (anti-resonance) quarter-wave interval.

Hi Mike, and thank you very much for your very quick response to my plea for help including your comments and suggestion. I will give it a try. Just a thought, I also have a 1:1 balun in my junk box. would this be worth trying for 80 metres albeit the antenna might not be ok on 40 metres then. I guess it would be looking for 50 ohms which is closer to the normal 100 ohms associated with a delta loop antenna--I think. Sorry my antenna theory is not brilliant.

>
> Hello David. It is highly unlikely that the 4:1 balun is seeing a suitable impedance on it's output side. Ideally it is looking for 200 ohms to match in the 4:1 ratio. The quick solution could be to break the loop at about 63 feet from the feedpointÂ and use it with the other section as counterpoise. You would then close the break to resume ops on 40 -10M. The balun is not wanted on 80M.

That's an interesting amplifier design, yet another example of what you can do with commonly available, inexpensive devices like the 2N/P2222. I would have done the biasing arrangement(s) quite differently so as to reduce the component count and improve the temperature stability.

Yes, very much so. I like the balanced common-base input stage as it is a more suitable termination impedance for the loop rather than the more typical high-impedance input, and the use of readily available parts is a very big plus. Designers who use scarce parts, and especially obsolete devices, can only discourage those with moderate building interest.

At the same time, I might add a centre-tapped inductor in the collectors of the input stage so as to normalize the signal gain over the desired bandwidth and retain the signal balance. I've tried using active negative inductors to cancel the loop inductance, but so far have had no success with that approach due to instabilities with common NIC circuitry.

7576. Question about a 50 cm loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-06-09 14:57:55 UTC
From: Horacio
Topic: 7576 Message: 7576

A radio friend -me too - owns a Kenwood R600. He has finished building a loop 50 cm with 12 turns.

I am asking to this group which is the impedance of this antenna and how to connect it to the receiver and where to connect it (to the 500 ohm input or the 50 ohm?.) To use twin wire or a flat ribbon TV (300 ohm) piece of cable?

Now that I've had the opportunity to look at this design in detail, I
can see that by looking at the loop antenna as a current source rather than
a voltage source there is a very credible wideband solution available that
will retain the radiation pattern characteristics, especially the null,
without the need for wideband matching circuitry. With that in mind, I've
initiated the design of an amplifier of my own similar in concept to that of
LZ1AQ but which includes a number of performance enhancements.

Horacio, see how the "pickup loop" is attached to this antenna:

http://www.mtmscientific.com/loop.html

http://www.mtmscientific.com/pickup.html

I have attached it with 300 ohm TV twinlead, with twisted pair of wires, and with small diameter audio coax cable. It works well in all cases.

This is my loop, and there is one turn of wire forming the "pickup loop" just inside of the main loop. The wire goes through small holes drilled, and lead to the binding posts on the rear leg of the X in that photo.

7580. Re: Pixel AM loop???

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-06-11 02:11:15 UTC
From: Jonny Boy
Topic: 7577 Message: 7580

Well it's high time somebody did this, glad to see it. I have a Wellbrook loop, am not entirely pleased. All of these loop snake-oil hustlers always hype the figure-8 pattern and the nulls. Excuse me, if you don't have the loop on a rotator, what good are these nulls? Speaking from personal experience, mind you. And if you add a rotator, congratulations, now you've blown $500-$600 on a single lousy little antenna. You could have bought TWO active whips and put them on a phaser for less money. This is exactly what I intend to do next time, already have the phaser. This arrangement delivers 360 degrees of uniform coverage with a single HUGE sweepable null to play with, nice simple exterior setup (no rotors or rotor cable), maximum stealth... This is the smarter way to burn up 600 smackers for nulling and active antennas, I'm pretty sure.

That said, these Pixel antennas are different from Wellbrooks in some promising ways. I like that the amp and loop are separable so you can filter the amp input if you want. I would opt for the Pixel product for this reason alone (if somebody held a gun to my head and said I had to pick one or the other). As for the whole "Moebius" thing (see http://www.ece.unm.edu/summa/notes/SSN/note7.pdf) it's certainly intriguing. It means that this is a SHIELDED loop (sort of) which I understand do work better, i.e. somewhat less gain but more developed nulls. This "moebius" geometry is in a class all its own, like a hybrid of shielded and two-turn designs.

note: Pixel's own copy does NOT state or otherwise document that their product actually uses shielded construction. They just try to hypnotize me by repeating the word "moebius" over and over. They state "the RF PRO-1 Moebius Loop Antenna consists of a rigid light-weight ¾" diameter anodized aluminum 1 meter loop..." That is all. No mention of any internal, shielded conductive elements inside the tubing. No pictures of any such thing. Building their antennas this way would complicate construction, i.e. would make them more expensive. In other words, I need to SEE that they're actually doing this, and HOW they're doing it, before I'll believe it or put any stock in it. Does it even matter? Yeah sure it's "neat-o" and all but does it actually matter? I HATE marketing. The worst thing about hell is that all the marketers will be there.

yup, thats how i feel, 299 bucks for a three foot diameter loop? no way would i blow that kind of cabbage on an antenna, i would sooner go to the hardware store and buy a 500 foot roll of #12 stranded copper wire (about 50 bucks) and make my own loop strung up in the trees, Disclaimer: you dont have to use all 500 feet, make it using a formula (i think 1005 divided by the desired frequency for a full wave loop)

or...

if you want to use copper pipe or tubing that would work fine too, slightly more expensive than wire but pipe is rigid and can be configured in a more self supporting antenna.

i know some CBers that made half wave dipoles out of 3/4 inch diameter thin walled galvanized electrical conduit, they last about 5 years before the galvanized gives in to weathering and starts to rust.

even cheaper than copper wire is that aluminum electric fence wire found in any farm & ranch/feed store, you can get a 1 mile long roll for about 25 bucks.

Hi Group , Paul is the name , in Australia , i have been studying loop's for a month or so , i am also into Sw listening.

Made up a simple one a few day's ago out of a leftover piece of 21mm 8ft length(total-33"dia) house plastic water-pipe 4 turns inside with a 110pf fixed capacitor with a 10-60pf variable in parallel and a 1 turn pickup on the inside edge with 1 leg to shield and the other a 1000pf tap off , and trying it out , it's at fixed frequency of 1701khz .

I have just grabbed hold of some things to read in the files section .

Good to have a group , for Loop's.

Cheer's , Paul.

I dunno but i suspect it's hype ,,a name that sounds cool?

Anyway i would like to hear from anyone who has the Pixel loop? I am almost ready to pull the trigger and get the wellbrook ,but i think i like the pixel one better.

I dont have trees ,or room for 500 feet of wire ,no place to string any length up so the loop looks like a good idea .

In the USA, just as soon as a new ham is listed in the Federal Communications Commission (FCC) database he may operate on the air.

A new ham needs only the NVEC form in his possession showing he passed, and then he can operate using the call sign listed for his name in the FCC database.

The new ham should go here and register:

http://wireless.fcc.gov/uls/index.htm?job=home

There the ham obtains a "FRN" or Federal Registration Number.

Once he has the FRN he can log in and search for his name, find his new call sign, and operate.

I guess you must mean DX Engineering's AAPS-1P Electronically Rotatable Receive Antenna System, which they offer as a package for, uh, 1200 smackers minus a nickel.
http://www.dxengineering.com/Parts.asp?ID=2474&PLID=215&SecID=114&DeptID=12&PartNo=DXE-AAPS-1P
I'm sure this array is fantastic□ the phaser is probably the nicest ever made□ but that's not what I meant. In fact the ARAV2 active whips that go into this system are a lousy value, in my opinion (too expensive, limited bandwidth).

The system I have in mind is two LF Engineering H-900 Gain Probes (bandwidth 10 KHz - 60 MHz; 189 smackers apiece)
http://www.grove-ent.com/h900.html
combined with Timewave's ANC-4 phaser (199 smackers)
http://www.eham.net/reviews/detail/1138
which, while not equal to DX Engineering's NCC-1 (600 smackers all by itself), is both adequate and built like a tank.

Now, I may not have "looked at antenna prices lately" and all, but even a mouth-breathing jackass like me can see that these parts come in at less than 600 smackers total.

"Anyway i would like to hear from anyone who has the Pixel loop?"
Actually, what you really seem to want is people who have purchased BOTH Wellbrooks AND Pixels. I mean, who else is "fully qualified" to give you meaningful advice? I've owned one of the two, and here's my sage hard-won advice: forget about the loopster's marketing mumbo-jumbo; untuned active loops as a class are not what they're cracked up to be. That is, there are better more cost-effective ways to actually experience the benefits the loop manufacturers only pretend they're selling you.

TUNED loops are a different matter, but to get a manufactured one now you're really talking crazy money. For most hobbyists, the sensible place of loop technology is among hardcore geeks who love to build their own stuff and experiment. The further you stray from this, the more you're being a buck-toothed dork in Times Square buying the Brooklyn Bridge. This is bitter experience speaking. Screw me once, shame on you; screw me TWICE, shame on ME...

The one possibility I still find tantalizing for Wellbrook-type loops is building a "loop-sense cardioid array" (LSCA) by combining an ALA1530-plus with an LF Engineering H-900. The LSCA radiation pattern is MUCH more useful / discriminative than that of a simple loop. In fact, if Pixel is really serious about offering the world a better loop, they should look into building an LSCA *package*. The PRO-1 would make a perfectly good foundation. No physical separation is needed between the loop and whip, so the e-probe vertical could be integrated into the vertical support they're already using. The resulting whip-loop array would be practically identical to the PRO-1 and should achieve yagi-like performance in a physically sturdier package. Such a "loop" would actually be worthy of all the hype.

Hi
why not try a steerable array, using phasor software.

Instead of verticals in a square pattern, use 4 loops.
Google on Phasor and you should find details of Victors software.
You would need a sound card with a minimum of 8 inputs , and 4 softrock lite

Rx's , one for each antenna, now I know that the software will cope with a concentric antenna pattern using another 4 antennas inside the 4 , but that requires more softrock lites and a second sound card.
It works well, as I've helped a Ham in the UK get it all running.
It is not a project for a novice with little knowledge of electronics.
But I t would give you a steerable array, and I can't see any reason why you cant replace a large vertical with a loop. The radiation pattern needs to be as oval as possible, so close to the ground

Phasor is not a project to jump into without giving it a lot thought.

Ah Yes -- now I recall the capacitive tuning/matching
network using two caps, one a dual section. That's what
MFJ uses in their loop tuners. I may just
build one up someday. I run an FT-817ND and always was
an advocate of low power. It sure simplifies capacitor
procurement ;-)

As a result of recent illness I have given up my house
which was ham heaven and moved into an assisted living
residence where towers and wires are out of the question,
but a loop will provide a very satisfactory antenna.
I've got most of the materials ready and just need spring
to arrive -- it's late this year in Calgary!

Am I to understand that you're offended now because your previous "suggestion" was actually ... serious?? I was sure you were being sarcastic. I take back the Marconi jibe. Why don't you tell me more about these tiny Softrock SDRs. I've never heard of them before and I'm amazed.

OK
The softrock Rx is a small beast using an on board xtal oscillator running usually about X3 the receive frequency, although a ratio of 3/4 can be used as well, that is applied to a H mode mixer producing a I & Q output, Q being in quadrature to I.
That feed into the sound card on you PC, the faster the sampling rate the greater bandwidth you can see when using the core software and display software.

The receivers are about $20 ish in kit form, there are kits to cover most of the Ham bands up to 6 mtrs there is also a transceive version which is shipping now. For that price try one, there are several FREE programs to control your sound card and produce a display as a sprectrgram, ie. a panoramic frequency display. go to the main site and follow the links from there

www.softrockradio.org this link will take to to the main site

For a discretion of the phasor software and what it does goes to the ARRL QEX archives, the acticle was printed last year.

Best wishes

Dean, I'm intrigued also by the Pixel antenna.
But I've had a Wellbrook 1530 loop about 5 years now, and I'm very happy with it. I also have an Eavesdropper Sloper, about 67 feet, sloping from a second floor window, 30 feet high, to a tree branch about 8 feet high, oriented NE to SW.
I can't honestly say that one is better than the other, because there are so many variables. But if I were forced to have only one antenna, it would be the Wellbrook. It's a very good product. Maybe the Pixel is as good or better, but I don't have the space or resources to buy it and conduct an antenna "shootout" !
If you get the Pixel, we'd all be interested in your comments.
--jim

As for the whole "Moebius" thing (see http://www.ece.unm.edu/summa/notes/SSN/note7.pdf) it's certainly intriguing. It means that this is a SHIELDED loop (sort of) which I understand do work better, i.e. somewhat less gain but more developed nulls. This "moebius" geometry is in a class all its own, like a hybrid of shielded and two-turn designs.
I dunno but i suspect it's hype ,,a name that sounds cool?
Anyway i would like to hear from anyone who has the Pixel loop? I am almost ready to pull the trigger and get the wellbrook ,but i think i like the pixel one better.
I dont have trees ,or room for 500 feet of wire ,no place to string any length up so the loop looks like a good idea .

>Thanks Jim;

Finally ! A decent post ,without all the insult's and drama-
A little more about my situation ,there are several local station's that i would like to get most of the time ,i get them in my vehicle's so i see no reason that i should'nt get them at home ,but first i think i need to get an antenna as from the house a possible,not easy to do with only feet, instead of yards or miles around the house :)
anyway i would prefer a cheaper home built wire etc. but it's not possible and i really want to be able to steer the reception pattern,one of the big probs with wire setups. I even entertained the thought of buying a quad vertical setup but i think that's too much dough too spend on an antenna.
I'm pretty sure the wellbrook is a good system from what i've heard .
I'm also sure that any antenna system isn't perfect,so some ppl could be very dissapointed for some reason or other with any one of them.
I already have a short tower and a rotator so a loop looks like a good idea .
I've deployed several types of wire antennas ,some where more of a success than others but always have the same problem of directionality ,again the loop seems a good alternative,sry for going on forever here .
I'd rather get the facts before i just throw money and time at some thing ,that's why i keep bringin it up .

Thanks Jim

7600. Moebius shielded loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-06-13 22:33:05 UTC
From: Andy Ikin
Topic: 7600 Message: 7600

Hello Folks

Having read Chris Trask's paper "Mastering the Art of Shielded Loop Aerials" plus Dr Carl Baum's original paper on the "moibous strip loop". I decided to try out this loop architecture to see if there was any benefit compared to the use of a single turn low inductance balanced loop/ amplifier combination. My inital thoughts were; that the E-field noise imunity would be the same, but there may be a problem with HF gain.

My reasoning being:

1. With Moebius shielded loop, the outer tube is 2 halves of one turn of the loop (The loop is effectively 2 turns). Hence, the E-Field is not screened from the outer. Therefore, I don't believe that this loop is shielded in the conventional sense.

2. If my reasoning is incorrect (the Loop is shielded), does it make any difference compared to a single turn un-screen balanced loop? The answer is no; with a single turn balanced loop, any induced E-Field cancels out due the 180 degree output phase difference, providing that the antenna aperture is small in terms of wavelength. The reduction in E field rejection is also afforded by using a low input impedance/balanced amplifier.

3. Many years ago, I compared E -Field rejection of an ALA1530 loop verses a shielded version. I couldn't detect any difference.

4. Single and multi-turn loops deliver the same power output, providing that they have the same area/volume. Only the Current/Voltage and impedance relationship is different. This feature is often missed by loop antenna constructors!!

5. Therefore the Moebius shielded loop provides 2 x the Voltage and 1/2 the Current and 4 x the impedance of single turn loop .

6. The capacitance of the Moebius is an order of magitude higher than a 1 turn loop, this combined with higher loop impedance may affect the HF responce.

7. It may not be a good idea to surround a loop antenna with a screen that is connected directly to the antenna feeder screen that could have high common mode noise or powerline noise!!!!!!

Notwithstanding the above. The Moebius shielded loop was constructed using 38inch diam. aluminium tube, 3/4inch OD. with a split at the top of the loop, the inner wire was made from the outer braid of RG58c. This loop is effectively 2 turns with a loop inductance of 10uH (res. freq is 5.1MHz). This compares to 2.2uH for a 1 turn loop with above size of tube.

Both loops were compared using a test set-up that provides a H -field from 50kHz to 30MHz.

The amplifier used on the Modebius loop was a New high gain ALA1530 loop amplifier with the FM band filter caps removed so as not to slug the HF response. The single turn loop used the same loop amplifier with the FM band filter caps fitted.

Note. compared to the current production ALA1530+, the new ALA1530 amplifier increased the LW and MW gain by approx. 10dB and 4dB respectively. The upper HF gain is increased by approx. 5dB. Also there is an increase in the OIP2/3.

To summarise the results.

Between 50 and 200kHz the Moebius provided 3.5 to 6dB gain increase. This was only due because the amplifier input z was more closely matched to the loop z.

From 500kHz to 10MHz the New ALA1530 has 1.6-4dB gain increase

Between 12MHz and 16MHz the Moebius gain peaked about 1dB above the new ALA1530

Between 18MHz and 30MHz the gain of the Moebius drops off significantly by 2-12dB.

I also performed some on tests with both loop types mounted directly under 11kV power lines (a noisy E Field source). Both antennas provided a similar noise reduction compared to an active dipole antenna.

From the above, it is quite clear that the Moebius shielded loop is not suitable for an LF to HF broadband loop. The loops' HF responce drops off due a too a high Inductance and capacitance.

Other issues; the split in the shield of the Moebius loop mechanically weakens the loop. Hence, a top support is mandatory. This would add to production cost and shipping costs.

Regards

Andrew Ikin

Andrew,
Thank you for going to all the trouble to provide us with an actual test
of the Moebius Strip Loop. That had been lacking in the literature.

You'll notice in my paper (which you mentioned) that I provided a
description of a top support for the Moebius Strip Loop which can be
interchanged with a top support for a "normal" shielded loop.

I wonder now how the performace of a Moebius Strip Loop of a given
diameter would compare with a "normal" shielded loop of twice the diameter?
My take when looking at the two was that the Moebius Strip Loop could

deliver comparable performace, so that there is a saving in both size and material cost.

Several years ago I compared a split shield loop to a non-shielded version and found no significant difference in the electrical noise immunity or gain. If anyone has actual empirical and numerical results of the two versions please advise. Thanks. Regards.

Chris,

Unfortunately, my aluminium bending jigs are limited to loops of 38 inches and 43 inches diameter. So I can't do what you ask. I don't honestly believe there would be any gain advantage.

Getting back to the results, I didn't fully explain the reason for the apparent gain increase of the Moebius between 50-200kHz.

The ALA1530 amplifier input impedance is designed to track the loop reactance over 6 octaves from approx. 500kHz to 32MHz.
Hence, the amp. z-in at 500kHz is about 10 Ohms (loop reactance is about 7 Ohms). As the loop reactance rises with frequency so does the amp. z-in. So over this design bandwidth, the loop/amplifier is approximately Power matched. You may ask why I have done it this way, as apposed treating the loop as a current source and using a very low z-in trans-impedance amplifier (eg. Rhode and Schwarz HFH-22).
The reason is; when the loop reactance is high compared to the amp. z-in, this high reactance limits the available current to the amplifier i.e. there is a miss-match. Hence, this why designers using current amplifiers try to make the loop reactance as low as possible. So you can see that by having an amplifier tracking the loops reactance has considerable advantages. As far as I know this is a unique feature.

However, the z-in of the ALA1530 amplifier starts rise below 200kHz to about 30 Ohms down to 50kHz, hence there is an loop/amplifier miss-match that reduces the loop sensitivity on the LW band. For the ALA1530 this is a positive feature to prevent antenna/receiver overload or IMD from Mega Watt Broadcast stations.

As the Moebius loop has 4 x the loop reactance as the 1 turn loop, then the higher z-in of the amplifier at LF will see the moebius as a better match. Hence the apparent gain increase.

Kind regards

Andrew

Mr. Ikin:

Have you done any experiments with the "loop-sense cardioid array" concept pioneered by Ron Schatz in the 1960s (NRC reprint A20; DX News magazine)? From what I gather, if a loop and a matched vertical are phased together using a common "splitter," this somehow transforms the loop's inherent "figure 8" pattern into a single unidirectional lobe, which has its uses. This lobe can then be swept by physically turning the array. No physical separation between the loop and whip is necessary, unlike with phased arrays of identical antennas. The main design challenge is scaling the loop and whip so that this effect is maximized and consistent throughout their shared bandwidth.

Also, I believe loops benefit from shielding not because their gain is increased but because shielding makes the nulls wider and more absolute; I seem to remember this from the ARRL Antenna Book chapter on loops.

I had thought the shielding to an incident (and I think symmetrical) interfering RF dielectric field E was active in the M=2 version (and M=3). Here the loop voltages induced from the E field effectively cancel and one is left with only (or nearly only) magnetic field H voltage induce of the intended signal.

Thus the shielding should be effective and noticeable.

Jonny, I an not familiar with Ron Schatz's work. However, I have done some work with "loop-sense cardioid array" for LW and MW only. This used an ALA1530 plus an Datong AD370 Active dipole. Both items were mounted on the same antenna rotator!! These were phased using a Wellbrook APU100 phasing unit (no longer in production). The problem with type of set-up is the Phase and Amplitude adjustment is very critical. Replacing the AD370 with a 30m longwire appeared the provide more stable nulls. Also the set-up requires constant adjustment even for small frequency changes. To put it an other way, it is pain in the butt to use. The critical problem is the requirement for a 90 degree phase shift across a wide bandwidth. To try overcome the critical phasing issue I did experiment with an up-conversion phasing system, this used two Mini-Circuits Double Balance Mixers (DBM), with a 90 degree phase phase shift (+/- some variation) on the local oscillator. Then both DBM outputs were combined and down converted by to LW/MW using another DBM. It did provide the wideband phase shift, but it needs some more work to finish it off. However, I don't see that this type phasing system providing the performance of a 2 loop phased array using a variable cross-fire phasing, providing you can accommodate 30-40m antenna spacing. The Wellbrook variable cross-fire phasing unit can also be used 2 active whip, active Flag and active K9AY antennas. This is the only commercial phasing system to provide a near constant F/B from 500kHz to 2MHz without endless knob twiddling. The directivity of the dual K9AY array is on par with 4 square array or a 600ft beverage. The down side of the K9AY array is that is needs a lot clear space so that nearby structures don't disturb the antenna E/H field relationship. The price of this system may seem high but is a fraction of the cost the dual whip phaser system mentioned in recent post (Pixel am loop). So if the above sounds bit complicated, consider a 2 loop K9AY with remote variable termination, this will give 360 degree coverage and optimum nulling and relatively small foot print. I still make them order and it works from 60kHz to 2MHz, it is dream to use compared to pair of antennas using a standard phasing controller, however, the absolute null depth may not be as good especially for high angle skywave.

My experience suggests that Shielding only improves the loops "nullability" if the loop or its amplifier are not balanced properly. Maintaining the balance of a tuned loop can be difficult, hence the use of a shield.

Kind regards

Andrew

Lex, the nominal amplifier gain as measured in a 50 Ohm system is approx. 29dB at 500kHz. the NF is about 2dB. I just don't have the time to measure the power gain or NF at difference freqs. with differing input z.

Have a play with a softrock kit depending on which you get, It will give you a
taste of SDR. Now if you like what you see, have a serious look at HPSDR,
If you use the HPSDR off the TAPR group you will have full transceive with up
to 100W, there is Open HPSDR as well this group broke away and there are some
ver good boards there.
HPSDR uses a back plane board so all the other boards plug into it.
Its good, but too expensive for me :(

As your in the stage of not having a radio its worth taking stock of your
options, do you go and buy an expensive HF or VHF rig or go down the SDR route.
Softrock is low cost, and I guess you should know which end of the soldering
iron gets hot.
You should be able to get a softrock Rx for about $20.
Dont run into it splashing $ everywhere, take your time and evaluate you
options.
Borrow a rig for a short while if you are really excited and raring to go.

HTH

Andy:
Thanks for your response. Can we roughly assume that your amplifier has relatively flat response up to 30 MHz or is it shaped to go down as a function of frequency since the loop's output voltage goes up as direct function of frequency?

Also can you elaborate on your test setup for the tests you did on the Moebius loop vs the ALA1530+? For example, what did you use to generate the magnetic field from 50 kHz to 30 MHz? What was the distance between the magnetic source and antenna under test? How did you deal with standing waves, etc ?

First, Congratulations on the new call!

First, the convention is, all bands below 10 Mhz are Lower Sideband, except for the five 60 meters frequencies. (an aside, they are a waste of time, don't get too concerned over 60 meters, there are better places to hang out).

Frequencies over 10 Mhz are all Upper Sideband.

10 Mhz (30 meters) is CW and digital only, no phone at all.

Morning 40 meters, Lower Sideband. Sometimes this band closes in the middle of the day. It opens again the the mid to late afternoon and stays open into the early evening, sometimes an hour or more after dark.

20 meters, Upper Sideband, is open in the middle of the day. The more sun that heats up the upper atmosphere, the better. To a lesser extent, 17 and 15 meters, too, though there are times that 20 meters is open, 17 and 15 meters not.

15 meters is a great place to QSO South America on days when the band is open. Getting 5-9 reports back when you only have 100 watts and a simple dipole is pretty common.

10 meters is rarely open these days.

Beginning about sundown, it's time for 80/75 meters, Lower Sideband. And this band stays open until just after sunrise. Most of the nets are concentrated in the 3.870 - 3.950 Mhz area, but some are lower.

Of course, this is all phone.

PSK31, on 20 meters, 14.070 Mhz. On 40 meters, 7.070 (mostly US) and 7.035 Mhz (lots of European and other dx users). Same times as above. Often you will see 20 meters begin to close down, and then see the same hams down on 40 meters as that band opens.

Right in the middle of 40 meters we still have the African AM broadcast station, but they were supposed to have vacated the frequency.

You can stay busy with just 80/75, 40, 20, and 15 meters. If you work days, and can only play radio at night, you should put your effort and wire into 40 and 80 meters. If you only play radio on the weekends, during the day, you'd want at least 20 meters.

Once I knew WHERE (freq) to look, and what MODE to listen to, I was picking up a lot more stations. So, a waste of time checking out 80 meters FM during the middle of the day, or

Lower Sideband on 17 meters at night.

First, Congratulations on the new call!

First, the convention is, all bands below 10 Mhz are Lower Sideband, except for the five 60 meters frequencies. (an aside, they are a waste of time, don't get too concerned over 60 meters, there are better places to hang out).

Frequencies over 10 Mhz are all Upper Sideband.

10 Mhz (30 meters) is CW and digital only, no phone at all.

Morning 40 meters, Lower Sideband. Sometimes this band closes in the middle of the day. It opens again the the mid to late afternoon and stays open into the early evening, sometimes an hour or more after dark.

20 meters, Upper Sideband, is open in the middle of the day. The more sun that heats up the upper atmosphere, the better. To a lesser extent, 17 and 15 meters, too, though there are times that 20 meters is open, 17 and 15 meters not.

15 meters is a great place to QSO South America on days when the band is open. Getting 5-9 reports back when you only have 100 watts and a simple dipole is pretty common.

10 meters is rarely open these days.

Beginning about sundown, it's time for 80/75 meters, Lower Sideband. And this band stays open until just after sunrise. Most of the nets are concentrated in the 3.870 - 3.950 Mhz area, but some are lower.

Of course, this is all phone.

Thanks!

I'd read somewhere the reason for the convention about USB/LSB was from 20/40m SSB radios built using an IF around 10MHz, so USB on 20m inverts to LSB on 40m.

I'm still trying to get a radio... I'm still recovering from two years as a Starving Student(tm) so I'm trying to either sell some tools or trade them for ham radio gear.

Hi Steve
If your skint have a lock at softrock, if you dont mind building it and its a cheap way to get on air, you all ready have a comnputer, so why not have a look at Software defined Radio.
Depending on whos software you use you have the receive capability of rigs costing as mush as your in debt with your student days, and softrock has transmit capability as well

Best wishes

From: vk6mb
Topic: 7621 Message: 7622

In addition, I have a 20-300pF 7.5kV Vacuum Cap and a 3.5m x 1.2m 'groundplane' roofrack on my Toyota Troop carrier and I can make the vertical part from 25mm copper pipe, but then I need to know formula for working out placement of the gamma match etc. I can drive the cap with a screwdriver motor, then I need to find a controller for that as well.
So any help appreciated

Hello,

Do a lot of you use an SGC tuner with your wire loops? How do you connect the wire to the tuner for temporary applications? Thanks.

Hi Frank,

I have a 237 which I use with a portable loop (ripped off SGC's "Stealth" Antenna!). Not liking the connection arrangement provided by SGC, I did a mod. to fit two 4mm binding posts on the cover where the "hot" terminal is. Much quicker and neater.

It's not rocket science, but you have to be careful removing the cover to minimise damage to the sealing gasket. Once inside, you have to provide an additional "cold" wire to the pcb. If you want more info and/or pics, contact me off list.

7629. Active loop amplifier

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-06-30 04:59:13 UTC
From: vbifyz
Topic: 7629 Message: 7629

I'm going to try and assemble something like this:
http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna.htm
Anybody tried a different amplifier for such loop? I've found a nice opamp from Intersil, EL2125 that has amazingly low voltage noise and enough bandwidth. Ordered samples today. Any experience here with this or similar parts?

I'm in the process of designing an amplifier similar to this that should have better noise and IMD performance. The progress of this has been hampered by other obligations. I'm using this project as a basis for the mechanical design of shielded loops and Moebius Strip loops.

Avoid using opamps for active antenna design. Despite their low noise and distortion specs, they still do not compare with those of discrete devices.

Hi Chris,

I don't fully agree with your statement that OPAMPs are not good for active antenna's . I made some active whip amps with a standard FET-input Opamp from AD with very good results regarding linearity.

Enclosed is a document that gives an idea of the results.

Best regards,
Patrick Reynaert

Hi Chris,

I understand that this requires proper analysis, but in my case the design goal is not only the wide dynamic range, but the deep null as well. From what I've read so far, this requires the loop to be "ideally magnetic", i.e. insensitive to the electrical field. This is achieved by using Alford loops (http://www.pa0sim.nl/Alford%20loop.htm), or reducing the amplifier input impedance, or both.

Reducing the input impedance requires high open-loop gain and flat phase response of the amplifier. I think opamps can be better for this particular application (deep null), but again, detailed analysis is required.

No, reducing the input impedance has absolutely nothing to do with high open-loop gain. I achieve exceptionally low input impedances with common-base amplifiers using a very simple technique that I patented:

http://www.home.earthlink.net/~christrask/MWSCAS99.pdf

"Common Base Amplifier Linearization Using Augmentation," RF Design, October 1999, pp. 30-34.

"High Efficiency Broadband Linear Push-Pull Power Amplifiers Using Linearity Augmentation," Proceedings of the 2002 International Symposium on Circuits and Systems (ISCAS 2002), 28 May 2002, Phoenix, Arizona, Vol. 2, pp. 432-435.

Common-Base Amplifiers with Linearity Augmentation, US Patent 6,271,721, 7 August 2001.

And it will outperform your monolithic devices any day of the week.

Date: 2010-07-03 00:19:09 UTC
From: gareywittich2000
Topic: 7636 Message: 7636

Has anybody tried to make their own equivalent RF systems DX-1 Mk 2 Loop antenna ??

I like to build things and see this as a good project.

RECENTLY saw an article about tuning a Loop Antenna using Varactor Diodes (which enables REMOTE TUNING). Looking for Article again but can not find it. Do you know where it was ??

MANY THANKS,

Garey Wittich Santa Monica, CA

Gary, the RF Systems DX-1 Mk2 is not a loop antenna, the so called crossed loops are a just a capacity hat for an active whip antenna. I believe the reason for the use of the capacity hat was to overcome signal loss due to the use of high input capacitance FET. If you are interested in building active whip antennas join the 2N5160-Antenna group and have look in the files section. I believe that Chris Trask has some designs on his excellent web site.

Chris has already mentioned the Loop Antenna using Varactor Diodes.

I think that Richard (Rick) Karlquist has also written on article on the above, but I can't lay my hands on the web link.

Kind regards

Andrew Ikin

7644. New ALA1530

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-07-09 19:34:33 UTC
From: Dominique Kremp
Topic: 7644 Message: 7644

Hi all,

There is a new antenna in the Wellbrook catalogue: a re-designed ALA1530 !

http://tinyurl.com/2fkenpp

I could test it and compare it to the "old" version of the ALA1530.

It's very impressive indeed. It has more gain on LW-MW (approx. 10dB and 4dB respectively) and the real improvement is above 9MHz (5dB gain). I'm just hearing RFI at the moment (1930) on 15300KHz. The signal is clear and comfortable with the new version whereas the old one brings out 50% hiss ! Incredible !

Fine antenna indeed !

The new ALA1530L is its sister. It has less gain on LW-MW than the new ALA1530 and the same gain above 9MHz. It should be a good compromise for receiving stations which MW transmitters are close by.

I didn"t test it.

See you

I just posted the schematic of an amplifier for wideband active loop antennas. The design is complete, and testing shows that OIP3 performance is around +45dBm. I have not yet done a NF test. I will have a full write-up of this design later, and it will include the details for winding the various transformers as well as Mini-Circuits substitutes where suitable.

Power (+12V to +15V) is supplied by way of the feed cable. I like to have all of my active antenna designs use the cable for power and/or tuning so as to simplify the installation. The PN4416 (Q6) provides noise immunity for the biasing reference and is quieter than using a 3-terminal regulator. Transistor Q5 provides thermal compensation for the biasing point.

7652. Re: Wideband Active Loop Amplifier

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-07-16 15:41:49 UTC
From: d29602960
Topic: 7647 Message: 7652

Hi Chris and the group,

I just downloaded the schematic of your wideband loop antenna amplifier and at the risk of sounding a little juvenile it looks truly "awsome" with some very interesting features.

The idea of using a low impedance loop antenna with wide bandwidth as a "utility" receiving antenna for general SW and ham listening has been a topic of interest here for some time. The nearest I came to filling these requirements was to adapt a loop design by John (G8CQX) which has served very well for a number of years now.

http://www.qrss.thersgb.net/active-loop-receiving-antenna.html

I have been looking for something to replace my version of Johns loop for some time with a view to improving OIP3 performance and linearity in general. Your design looks very exciting and I look forward to trying it out soon.

If I may I should like to ask a couple of questions?

Would I be correct in assuming that because of the negative active feedback that this design will work well with other devices such as 2N3904 or 2N2222 etc?

How "critical" is the layout likely to be? For example, would this design lend itself to "dead bug" style construction over a ground plane providing device leads etc are kept short and direct?

And finally, under the list of components in the schematic the transformers listed as "T5, T7-2:2:1 on T50-6 toroid", should this read "T4, T7" or have I miss-read the diagram?

Thanks for sharing your expertise with the group and I look forward to trying this one out.

73,s to everyone on the list.

Des (M0AYF)

The goal was to design an amplifier that would equal or exceed the performance of the Wellbrook AL1530, while at the same time keeping the cost down. Many of the passive components (resistors and capacitors) were necessary in order to provide temperature stability without requiring that all five transistors be matched. That would not have bee received well.

>
> Would I be correct in assuming that because of the negative active

First, there is no negative feedback here. Transformers T2, T3, T5, and T6 amplify and invert the error voltage at the emitter and apply it to the base. It's a method I patented called "augmentation". It improves the IMD performance and dramatically decreases the emitter input resistance. I tried other transistors such as the 2N2222 and 2N4401, but the higher gain of the MPS6521 provides about 10dB of OIP3 performance.

I built the rototype on 1/10" grid board, which you can see in my earlier publications. You can easily cut out the circuit on double-sided PC board material. The circuit was laid out so as to facilitate a one-sided PCB layout with a solid ground plane.

Hmmm... That should have said 25V. Temperature coefficient is not im
portant, but ESR (equivalent series resistance) should be low.

Have you tried anything like the ZTX690B or a FZT491A? The Diodes/Zetex transistors have really impressive Betas, higher power dissipation capability, low resistances and are potentially very low noise. I found one application note about a low noise amplifier (audio) on the Diodes website:
http://www.diodes.com/_files/design_note_pdfs/zetex/dn11.pdf

Both parts have a minimum ft of 150MHz. Cobo is 16pF and 10pF respectively.

Also, what is the target base bias supply voltage? I'm thinking I might want to select the value of R5 to account for part-to-part variation in Q6.

Haven't tried either of those. To get the best IMD even when using augmentation, a higher hfe helps. I'm still experimenting with this, trying to get better performance. Yesterday I removed transformer T1 and connected the antenna directly to the Q1 and Q2 emitters, which improved the low frequency performance.

Supply voltag is 12-15V. I presently have a 100-ohm potenetiometer for R5 so as to see the effects of changing the bias current. Going from 15-20mA has little effect on OIP3.

Chris Trask wrote on the July 16.

"I just posted the schematic of an amplifier for wideband active loop antennas. The design is complete, and testing shows that OIP3 performance is around +45dBm. I have not yet done a NF test. I will have a full write-up of this design later, and it will include the details for winding the various transformers as well as Mini-Circuits substitutes where suitable."

Hello Chris,

I have looked at your schematic and I think there are a couple of errors:

The emitters of Q1/Q2 and Q3/Q4 are DC connected via the T1 and T4, so we may have a thermal runaway problem i.e. the transistors are sharing the same RC bias. So I think you need to make sure that each transistor have individual RC bias.

T7 may saturated and cause low frequency IMD as it has the DC power running through the secondary winding. A simple way to avoid this would be to use 1 uF cap to dc isolate the secondary of T7 and feed the dc from the coax via a 470-1000uH choke to T7 centre tap.

Kind regards

Andrew Ikin

I don't think there will be a thermal runaway, but any mismatch between transistors will result in unequal currents through them, affecting the symmetry of the amplifier.

My question is about the second stage: Chris, do you really want its input impedance to be very low? I think this will result in non-optimal load for the first stage.

Regards,
Mike

Nice thing about the augmentation is that it helps even out any small imbalances between the two transistors. And ensuring good DC balance and avoiding thermal runaway is a fairly simple task that won't require any matching of transistors. It will make the construction of the coupling transformers a bit unusual.

>

Yes, but not necessarily as low as it is as shown in the present schematic. The reason for keeping it low at this point of the design is to determine if the basic configuration will give me the desired high frequency performance. With the upper 3dB limit presently at 45MHz, I can afford to sacrifice some bandwidth at the interstage transformer T4, and the scheme I have in mind will relieve some construction requirements of that transformer. The collector loads presented to Q3 and Q4 by T7 pretty much dominate the high frequency cutoff.

Hi again Chris and the group,

Many thanks for answering my questions about the loop amplifier and for clarification of the "augmentation" function.

Following your posting I re-read your paper "High Efficiency Broadband Linear Push-Pull Power Amplifiers Using Linearity Augmentation," and think I have a better understanding of the circuit funcion now.

http://home.earthlink.net/~christrask/ISCAS02B.pdf

Having said that I suspect more questions may follow when I assemble and test the circuit for the first time :-)

Thanks again.

73,s to all.

Among the goals of this design was the need to make it suitable for all forms of magnetic loops, including shielded and Moebius Strip. The Moebius Strip loop presented a drving point in the design as the antenna proper is connected to ground, whereas the antenna proper in a shielded loop is isolated from ground, same as with an unshielded loop.

There is also a strong need to avoid any form of circuitry that would introduce an arbitrary phase shift or amplitude variation, such as matching capacitors for transformer leakage inductance. The untimate goal of the amplifier is for use in an array for wideband interference cancelling and/or electronic steering, and it would be desireable to keep relative phase and amplitude variation between two amplifiers to less than 5 degrees and 0.5dB, respectively. I designed the control head for that a year and a half ago, but a suitable wideband antenna array has been elusive until now.

Hi Chris,

I would appreciate any comments you may have on this design;

http://xephemera.blogspot.com/2009/08/16-30-mhz-broadband-low-noise-loop.html

It is not an original - the circuit has been around for years.

In my noisy urban and tropical environment I can detect no difference when switching to my ALA 100L-1 amplifier.

Some Finnish hams reported that the design was pretty good in quiet environments compared with the Wellbrook.

I now use both amps on separate loops orientated 90 degs and switch between the two.

I've seen a number of amplifiers similar to that. The first one that comes to mind is that of the British fellow who has an extensive online presentation of a large loop antenna. Can't recall his name or the URL at the moment, but I'm certain that there are list members who will readily recognize who I'm refering to.

It would be interesting to compare the radiation patterns that result between high input impedance and low input impedance amplifiers used for wideband active loop antenna applications. I suspect that the former approach would deteriorate the null.

One item I find missing from this design is an input BalBal transformer. Such a transformer would serve a number of uses, in particular providing a degree of immunity from common-mode interference such as lightning strikes. It would also provide a ground reference for the antenna proper, and in addition would allow the two transistors to have an identical base voltage. The limiting diodes would be placed across the primary side of the transformer.

I would also disconnect the two emitters, have a separate biasing resistor from each emitter to ground, and then a suitable capacitor between the two emitters. Then the two capacitors from the collectors to the output transformer primary winding can be eliminated. The 1:1 UnUn output transformer could be replaced with a 1:1:1 BalUn, the centre tap of the primary connected to the supply line. This would increase the P1dB a bit plus raise the gain by an additional 6dB.

Chris

I tried a similar design of my own. Linearity wasn't good, maybe because I only had about 5ma current through each transistor. I could hear products from nearby AM band stations up to 7-10MHz. It was a quick prototype without proper shielding, so it also suffered from instability because of the feedback from the output transformer (on a toroid, not a binocular core) back to the loop.
Nulling wasn't good because of the common mode electrical component pickup.
I guess when properly done, the design can work acceptably.

Mike

IMD is a serious problem for active antennas near broadcast stations. I have a 10kW AM station less than 10 miles from me that can be easily picked up with a scope probe shorted to the ground lead. Common-mode interference suppression dictates using balanced circuitry, even to the point of using twinax cable for the feedline.

I would replace the 47 ohm emitter resistance with a J310 fet with gate connected to ground to make a nice simple constant current source.

This should improve the signal.

Thanks Chris

If I get time I will build another with a Bal Bal input as you suggest. First I will probably stick with the conventional long-tailed pair config, perhaps incorporating a constant current source as someone else suggested. At present the current drain is about 30mA in each transistor.

(I always tend to pot my amps because they quickly corrode in the tropics nomatter how careful you are. Although this means once potted never again accessible !)

You'll probably notice an improvement in the IMD performance when you make that change as it will help bring the amplifier into closer balance.

I was wondering what the purpose of the potting was. Have you considered using stud-mounted insulated heat sinks in place of the radiating fins?

Hello Chris

With your experience should the board be Through Hole design or surface mount

Would the Through hole make a difference in RF ?

I checked quick and MPS6521SM seems not to be available but I did not spend too much time

I will go with through hole design for now since that would be the easiest to make and provide as a kit .. for most.

Vahe

I'm in the process of designing an amplifier similar to this that should have better noise and IMD performance. The progress of this has been hampered by other obligations. I'm using this project as a basis for the mechanical design of shielded loops and Moebius Strip loops.

Avoid using opamps for active antenna design. Despite their low noise and distortion specs, they still do not compare with those of discrete devices.

>

I've used both. The transformers, connector, 47uF capacitor, and transistors (plus a snall 10-turn pot used for R5) are all through hole. Everything else is surface mount. There's little to be gained in the way of board space going from a TO-92 to SOT-23 transistor package. There is, however, much to be gained using 1206 capacitors and resistors. I did this in order to get the best cost and performance. There is also a specific need for this to fit inside an electrical conduit fitting, which is far cheaper and stronger than an electrical utility box.

>

Not for HF and below.

>
> I checked quick and MPS6521SM seems not to be available but I did not spend
> too much time
>

Another reason for using through hole for that part.

Chris

Hi Chris and the group,

Regarding your recent posting(s) for the active loop amplifier design. I have now obtained some of the MPS6521 devices and intend to proceed with a first attempt at building your design.

Before I begin I should like to ask you a couple of questions and verify a couple of points if I may?

1) Transformers T1, T4 and T7. I propose to use T37-43 cores here with tri-filer windings. Will this type of core be suitable here?

2) I think you hinted in an earlier posting that a single turn loop could be connected between the emitters of Q1 and Q2 such that transformer T1 is no longer required. Are there any serious penalties if this is done?

3) For transformers T2, T3, T5 and T6 I propose to try a pair of matching ferrite beads side-by-side or more of the T37-43 cores listed above. Again using a tri-filar windings suitably connected. Anything to watch out for?

4 and 5) And my final two questions relate to Q5/Q6 in the schematic. I understand the use of Q5 to act as temperature compensation for the base bias supply but I am slightly unsure about the preferable device parameters for Q6. Since I do not have the device specified I would propose to use a J310 or similar. Is this likely to be OK and if so, what Voltage should I expect to see at the junction of R5, R6 and the gate of Q6?

I am hoping to have a prototype built over the w/end and will keep the group posted with the results.

BTW. Chris wrote:
I've seen a number of amplifiers similar to that. The first one that comes to mind is that of the British fellow who has an extensive online presentation of a large loop antenna.
*****

That would be my humble effort which I am hoping your new design will upgrade.

http://www.qrss.thersgb.net/active-loop-receiving-antenna.html

Thanks for your postings so far.

73,s to all.

>
> It would be interesting to compare the radiation patterns that result between high input impedance and low input impedance amplifiers used for wideband active loop antenna applications. I suspect that the former approach would deteriorate the null.
>
> One item I find missing from this design is an input BalBal transformer. Such a transformer would serve a number of uses, in particular providing a degree of immunity from common-mode interference such as lightning strikes. It would also provide a ground reference for the antenna proper, and in addition would allow the two transistors to have an identical base voltage. The limiting diodes would be placed across the primary side of the transformer.
>
> I would also disconnect the two emitters, have a separate biasing resistor from each emitter to ground, and then a suitable capacitor between the two emitters. Then the two capacitors from the collectors to the output transformer primary winding can be eliminated. The 1:1 UnUn output transformer could be replaced with a 1:1:1 BalUn, the centre tap of the primary connected to the supply line. This would increase the P1dB a bit plus raise the gain by an additional 6dB.

I would avoid using 43 material, especially for T1 and T4. It is very lossy, especially in low impedance circuitry. I got much better performance with 61 material, especially at low frequencies. You could use 43 material for T7.

I did try that, but then the issue of isolating the bias of the transistors came up and it became a nonviable solution.

The T37-43 cores would be the better choice. That's fairly high impedance circuitry there so you won't suffer losses as you would for T1 and T4.

The PN4416 has superb current stability with changing drain-source voltage (Vds) variations. See my evaluation of JFET devices at:

http://www.home.earthlink.net/~christrask/Paper016.html

You could use other JFETs such as the J310, but your supply noise immunity will degrade. They will, however, serve the purpose of getting the amplifier up and running. You should see about 1.65V at that junction, so that there will be 1.0V at the emitters of Q1 through Q4. It helps to use a 10-turn potentiometer for R6.

Also, I've changed the value of R3 and R4 to 33 ohms. This makes the collector current of Q3 qnd Q4 30mA, which takes full advantage of the collector load impedance of 400 ohms, improving the P1dB by 3dBm and a noticable improvement in the IMD products as you approach saturation.

Chris

Hi again Chris and the group,

Many thanks for your swift and in-depth response to my qestions regarding your loop-amp design.

After reading your reference located at ...

http://www.home.earthlink.net/~christrask/JFET%20Evaluation.pdf

I now understand the significance of the device you used for Q6 and will make renewed efforts to source this device for the final version. I will accept the reduced noise immunity due to the use of a J310 at this stage of testing in order to progress the test build.

Thanks also for your recommendations regarding ferrite types for the transformers.

I look forward to building/testing the loop amplifier antenna combination shortly and will keep everyone posted.

I have a sack of MPS6521's (TO-92's) picked up at a swap meet years ago.

If anyone needs some, I can give some matched sets of 4.
Matching is done using my handy-dandy Harbor Freight $3.99
multimeter which reads hFE, so it may not be much of a match
but better than a random assortment.

USA addresses only as postage would probably be excessive to
others. Please reply directly to jlkolb@.... No need
to clutter up the group with a bunch of "I want one" messages.

Greetings all. At the risk of sounding pretty stupid: I've been reading posts and searching around and want to make a loop, but I really don't understand the need for and design of amps/grounds/resistors in the loop, etc.....

I have a longwire and while that is basically understandable, I'm lost when it comes to the need for anything else to make a LOOP function.

Now, I'll stand back while you real experts throw pencil stubs and wire trimmings at me. But, if you mix in some basic facts or links where i can get smarter, I'll be most appreciative.

Thanks! keith

Hello Keith,

On the web many answers can be found for the questions you may have. For a start you might take a look in the groups archive section.

But getting entrance to a lot (perhaps too much) information is by doing a Google search. You could use the search terms:

Loop antenna

Passive loop vs. Active loop (that is the kind with the resistors, capacitors and transistors!)

Tuned loop vs. Untuned or broadband loop

Single turn loop vs. Multi-turn loop

Box loop, coax loop

When searching for loop antenna thes two came up immediately:

http://www.frontiernet.net/~jadale/Loop.htm

http://www.dxzone.com/catalog/Antennas/Loop/

These will give days of reading, both theory, practical examples and lots of other useful links.

>if you mix in some basic facts or links where i can get smarter, I'll be most appreciative.

Thanks! Keith<

The first thing about small loop is the pattern. A figure 8 with deep nulls off the sides that can be pointed at any bothersome noise sources.

The pattern only holds if the loop is balanced. There are a number of factors there, including physical proximity to things, shielded vs unshielded, matching methods, feed methods (all these can unbalance the loop).

Then there is selectivity, a small tuned loop is very narrow band. Can be built fixed tune, or with a variable capaciter. May be air variable tune by hand on side, remote tune by moror, or even remote via voltage if varactor. An untuned loop is wideband (no tuning).

The tradeoff here is signal strength. Loops are not high gain, the untuned loop is low output across the range. You may be using a nice receiver with very good internal pre-amps, or you may need to use an external pre-amp to get the signal up to the point your receiver is happy. With an untuned loop, you are taking everything equal, and amping and are more likely to have receiver overload issues due to strong local stations. With a tuned loop, you get a much higher (but still low) level on the tuned segment, and the rest of the loops range is much weaker. Tends to make overload less of an issue.

My 2c, I favor a varactor tuned shielded loop without pre-amp.

My reasons...

I am a HAM, so I already have multiple receivers with front ends much better than anything but the absolute best desktop or rackmount high end high $$$ SW receivers I have ever seen. I have good resistance to front end overload and multiple onboard pre-amps if needed, and receivers that will happily produce clean audio on signals so week the needle doesn't

move even with both pre-amps kicked in (provided there is a good S/N).

Shielded because it helps decouple from the environ and makes it easier to maintain balance (and the pattern). I am in a fairly urban environ, and plan to aim the null along the path of my street, putting the top dozen local noise sources in the null.

Tuned for better S/N, with my tuned segment 10 - 20db up from the out of tune background (should help with preventing overload from very strong local stations if I use the pre-amps, I have at least a dozen local stations that are S9+60 with pre-amps off and 18db atten on my main antenna)

Varactor tuned, so that I can control the tuning from the shack, with the actual loop sitting out behind the house.

Gain is presently 24dB. Haven't had the time to do the NF and OIP2 measurements, and the OIP3 is down in the spectrum analyzer noise. I need to set up an IMD bridge test setup to do the OIP2 and OIP3. Too many other unavoidable obligations getting in the way.

Chris

Chris,

I've been doing some SPICE simulations of the DC bias conditions using slightly mismatched transistors. At DC the bases and emitters of Q1-Q2 and Q3-Q4 are in parallel. For a Q1-Q2 Vbe mismatch of 11mV I get collector currents of 45mA and 27mA for Q1-Q2.

If the Q1, Q2, Q3 and Q4 bases are fed through four individual 2.2k resistors from the positive terminal of C16 I now get collector currents of 29mA and 31mA for the same mismatch. Probably C5, C6, C12 and C13 would need to be increased after this modification. I don't think this would degrade matching and might actually improve power supply rejection.

While augmentation minimizes errors due to transistor mismatch it seems that better bias point matching can only improve things further.

Thank you for that input. I solved the matching problem by way of rearranging the windings on T1 and T4 in a way that does not add any additional components and which simplifies the construction of T1, T4, and T7. I'm presently working on a full writeup of this design and I should have that plus the needed NF, OIP3, OIP2, and P1dB measurements completed by the end of this week.

7691. antenna question

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-07-25 19:40:21 UTC
From: Keith Davis
Topic: 7681 Message: 7691

Paul, there is some Ham DNA in the family. My dad was WB9YWL for decades. My older bro. is an inactive ham. I don't know if my wife will let me have another real hobby.
  OK......on with the stupid beginner questions, if you can take a minute and help me out I'll appreciate it. I have this shiny new ATS 909 and want to make a loop antenna for SWL late at night when i should be sleeping. I have the Sangean wind - up longwire strung across the bedroom ceiling now and my popularity index is falling by the day. Further, if a loop could be made that would sit behind the window blinds and pull in some more stations that would be fun.
Now, is there a design that a violinmaker could build with found materials? i can cough up some wire, perhaps a switch or two, any sort of frame needed and some discreet components like capacitors and resistors salvaged off old PC boards from old, dead electronics, etc.

I'm betting that there is more to a loop than just winding a loop. Right? I've been looking at the Kaito loop available different places but I'd rather not have to come up with the $40 or so to get one......unless it is NECESSARY.
Further, i have poked around online looking for and at loop designs but most of them seem to be for rather specific bands and needing very specific components.
So......if you can point me in the right direction i'll really appreciate it. Wish i could ask my Dad but he's been gone three years now. Thanks, keith

Keith, some good reading here:

http://www.hamuniverse.com/n4jaantennabook.html

You need to be careful... one day you'll wake up and find you are a ham.

For the AM broadcast band:

http://www.mtmscientific.com/loop.html

If you have a ferrite bar antenna in your radio, you need no other connection, just orient the antenna with the radio for best reception. If you have Ant and Gnd connections for an external antenna, which is what I need with my stereo gear tuners, you will need to add a pickup loop to the antenna. What I did was drill 1/16" holes about 1/2" in from the ends of each of the four arms, and ran wire through them to make a one turn loop, and connected the ends to a pair of binding posts (visible in the photo).

Connection can by by 300 ohm twinlead, twisted pair or coax.

This is my actual antenna in the photo:

http://www.mtmscientific.com/amcust.html

For SW, I did not build the kit from MTM, but built one just like it from parts around the shop.

http://www.mtmscientific.com/swloop.html

Also, if you have a SO-239 socket on your radio you can make a pickup loop from a piece of coax by forming the end of the coax (RG-58 or RG-6 is just fine) into a loop 10" - 12" diameter, and soldering the center connection from the tip back to the shield.

Paul
I looked on Amazon.co.uk

http://www.amazon.co.uk/Joe-Carrs-loop-antenna-handbook/dp/188212328X/ref=sr_1_1?ie=UTF8&s=books&qid=1280252248&sr=1-1

But it is a tad pricey at ?229.90 ! - I hope it's just a typo on their part.

regards

Yikes!!! My link showed it at $16.50 at Universal Radio. If you can't order from them, I'd be glad to get it and ship it for you.

7699. Wideband Active Loop Antenna Amplifier

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-08-01 16:57:02 UTC
From: Chris Trask
Topic: 7699 Message: 7699

I just uploaded a schematic and parts list for the wideband active loop amplifier that I've been working on. A number of changes were needed, especially at the input end, and this project is nearing completion. There will be a full writeup shortly. I've yet to measure the NF, and I want to machine a metal conduit body to mount it in.

Some of the performance is less than initially desired, but overall this has come out pretty nicely. Input impedance is 2.25 ohms (balanced), OIP2 is +80dBm, and OIP3 is +40dBm, all measured at 10MHz. Voltage gain is +30dBv. Power supply is 12-15V at 125mA.

7700. Dragon curve antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-08-01 18:02:44 UTC
From: jpopelish
Topic: 7700 Message: 7700

The dragon curve
http://en.wikipedia.org/wiki/Dragon_curve
is not a loop antenna, but this is one of the best antenna groups I know of, so I thought I would ask here.

I was thinking of antenna structures that would not exhibit sharp resonances (unlike tunes loop antennas) but would have an extended low frequency response relative to its physical size (comparable to loop antennas). and the dragon curve came to mind. Way back in my Commodore 64 days, I wrote a program that drew this curve with arcs, instead of straight line segments, so that the curve did not touch itself at the corners. I have often wondered what would be the radiation pattern of such a conductor.

The 4 curve tiling
http://upload.wikimedia.org/wikipedia/commons/0/0d/Dragon_tiling1.svg
seems (to me, intuitively) especially promising as a circular polarized antenna if the sections were fed with 90 degree phase shifted signals.

I found a patent on fractal antennas, but the test data is not very detailed, nor is there much in the way of theoretical insight.
http://www.faqs.org/patents/app/20090207087
http://www.google.com/patents/about?id=jtnJAAAAEBAJ&dq=fractal+antenna+dragon+curve

Has anyone, here, any experience with the radiation pattern and other properties of such fractal antennas?

I compiled that corrected version on my laptop, which has Adobe Acrobat 6.0, and which creates a 5.0 compatible file. My desk computer has 4.0, which creates a 3.0 compatible file that I much prefer. I'll compile it again when I return home.

Hi again Chris, Brian, Paul and greenfruit2002,

Thanks for the re-compiling the "Wideband Loop Antenna Amplifier RevA" doc. It now opens up with no problems.

BTW I use Sumatra pdf reader here, its less "bloated" than Acrobat and no "search bars" or spyware etc. Been using it for about 18 months, no problems except for opening pdf's compiled using the latest Adobe products.

Hi again Chris,

I just read the write-up on the broad band loop amplifier, its very detailed and very clear. it looks as though a good deal of work was involved. I would like to ask a couple of questions relating to the design if I may?

The input inductor (L2), would an T37-61 core be a suitable substitute for L2 with 4 turns bi-filer?

Neglecting C1/L1 in the revised design for the moment, how much difference in performance results from the use of L2 in the newer design as compared to the trasformer input (similar to T3 and T6) of the earlier design?

And finally, just out of curiosity how long does it take to prepare a write-up such as this?

73,

Des (M0AYF)

You can, but the inductance will be much higher due to the higher permeability and size of the core. With larger capacitors for C2 and C3 you can extend the frequency range down to 250kHz, at which time the coupling of T3 dictates the roll-off.

Quite a bit, actually. In the original design the input transformer became configured like the present T3. The input impedance was far too high to be suitable for use with a loop, so I conceded to using the coupling capacitors, which was simpler and less expensive that using a 1:1:1:1 transformer.

I should mention that L1 can be very easily realized by twisting the wires from the SO-239 connectors to the board for 2-3 turns and then slipping a small toroid or two over that. Really cheap, but provides the same function.

>

All together, about a full day. As I go from one write-up to another I borrow portions of previous ones, such as the early section on loop antenna impedance and the following portion on passive augmentation. Some things need to be repeated so that each write-up stands by itself.

From: cannonmandolin
Topic: 7717 Message: 7717

I can get a used variable condenser from an old radio, but it is one of the small ones with leaves of polyethylene between the metal plates. Can this be used in making a tuned loop? most specs call for an "air capacitor", but in salvage terms, at least in my life and work, they are quite rare.

I can see now that actually listening to the radio and keeping a log is just a small part of the whole picture, and perhaps a larger part is planning for, talking about, reading up and then actually building an antenna. heh heh heh So, it's about like fly fishing in that the fly tying, reel lube, rod building, wader fixing, etc far outweighs the time we are allowed to spend on the stream.

Short answer is YES.
The amount and type of insulation will really come into play when you are using the variable capacitor in a transmitter tank or antenna impedance match circuit. The insulation (air gap or poly) will set the amount of voltage that can be handled by the capacitor before breakdown/arcing occurs.

Hi again Chris,

Thanks for the swift reply to my questions relating to L2. Everything is understood now.

I had not fully understood the significance of L2 and its role in the filtering of I/P signals but after reading your reply and re-reading your write-up its much clearer now.

Don't forget that you're not limited to commercially produced capacitors. It's perfectly possible to build your own variable capacitor. All a capacitor is is two conductors separated by an insulator. So, you can dream up a lot of different configurations of conductors and insulators that will produce a capacitor. Then, all you have to do is vary the position of some of the elements to produce a variable capacitor.

For examples, do a search on "trombone capacitor", "book capacitor", and "rotary capacitor".

If you have any mechanical skills, there are even plans out on the web for building your own variable capacitors:

http://www.eham.net/articles/5217?
http://brneurosci.org/capacitor.html

> I can see now that actually listening to the radio and keeping a log is just a small part of the whole picture, and perhaps a larger part is planning for, talking about, reading up and then actually building an antenna. heh heh heh So, it's about like fly fishing in that the fly tying, reel lube, rod building, wader fixing, etc far outweighs the time we are allowed to spend on the stream.

The antenna tends to be the most important part of any receiver, since that is where the signal is the weakest, and the point where a degradation of the signal to noise ratio can occur the easiest. And, once the signal to noise ratio has been degraded, then it's generally impossible to improve it.

It worked for me. I have unzipped the downloaded file. It contains versions for Windows, Linux and Mac of a loop calculator. The windows version worked without problems. There are no explanations or instructions, but because you have to give in perimeter and width by moving slide bars it seems to be a calculator for a single turn loop made from foil.
Perhaps the Group memebr who uploaded this can give some background info?

I like that "build your own" idea......and, yes I have the skill and a couple shops full of tools and "stuff". Just not lots of radio "stuff". However, in my work as a professional violinmaker things do tend to accumulate on shelves and corners. And, lets face it, some "stuff" is just too good to throw away.

I have not read up on the trombone capacitor yet, but will do so.

Speaking of loops, i seem to remember an old radio in my childhood with an oblong loop pasted into the back panel of the cabinet, of course it was an old-fashion radio even then and i suppose it went out to the curb at some point. dang.

I bought a Kaito loop with the extendable spar in the middle. It took me a couple evenings to figure out how to get the best out of it, and may not be there yet, but it is working. I'm puzzled that it works about the same whether the little box is ON or OFF, only the tuning wheel does not function in the OFF position. No noticeable difference in whether it is switched to SW or MW. I've been hanging it in the window, right along with the aluminum mini blinds, so that may be messing with it. I'm waiting for the weekend and temps under 100 degrees and i'll take it out on the patio and hang it in a tree. Keeping a can of adult beverage nearby might help reception.

Thanks for all your help guys. I'll keep asking questions till i am half as smart as you all. That'll take about ten years.

keith

For the time involved, even if you have the materials, for the price you can buy one, making one is not reasonable.

http://www.midnightscience.com/catalog5.html#part2 $11 USD

http://www.stormwise.com/page3.htm (this page has 1, 2, and 3 section caps) $18 USD for single section.

http://www.mtmscientific.com/capacitor.html $17.50 USD

Wow......I guess I am not understanding the power involved in an antenna if it will actually ARC THROUGH the poly separators.

I read someplace that hanging a wire in your back yard and wiring it to ground via a salvaged LED will actually light the diode. I have not tried this but plan to soon.

OK, one of you all just made me smarter. Transmit antennas can develop voltage and arc, not USUALLY receiving antennas. Whew....

In about six decades i've managed to learn a lot of stuff.....just not stuff about radios. I've been too busy making a living I guess.
As usual, you guys are bailing me out. THANKS.

If it cools down much under 95 this evening I'm going to take my new Kaito out on the patio and hang it as high as I can and see what's available to listen to. Hopefully the 'skeeters are not too hungry tonight.

While in the Navy, we could light small florescent tubes from our
receiving antennas, but that was with
two 500 watt transmitters continuously keyed, and spacing less than
the length of the ship. I wouldn't
expect to light an LED from a receive antenna unless you are within a
few blocks of a broadcast transmitter.

Likewise, for receive use, a variable cap with poly separators should fine.

I'm sold on Loops now I guess. I got outside last evening and humg my new Kaito on a bamboo stick about 20 feet long and let the lead trail down to me on the patio. I was hearing stations I've never heard before, and the tuning wheel, though pretty sensitive, was doing wonders.

Now I'll have to dig in and figure out where to get some copper and build my own, permanent OUTSIDE loop.

Keith,
Making a varible condensor is great fun in my opinion.
Ofcourse you can buy the nessesary components.
Starting build your own most simplified receiver
is fun and still students do that....
http://www.youtube.com/watch?v=AWL7hLEVSHQ

Google for "selfmade variable condensor" and "crystal radio".

Have fun !!!

Well, that's gotten twisted in the telling and retelling.

Power harvesting has been a hot item lately, but not to charge car batteries. EDN, Design News, or EE Times had an article lately on using static electricity or random RF fields to charge very, very low power capacitor storage devices for use in extremely low duty cycle, extremely low power devices. We're talking microwatts/microjoules.

There is actually a spark gap oscillator involved in one design. A really, really tiny spark gap.

> Wow.....I guess I am not understanding the power involved in an antenna if it will actually ARC THROUGH the poly separators.

Transmitting loop antennas, especially small ones, can have VERY high voltages and circulating currents even at moderate power levels.

That's why some people who make small transmitting loops go out of their way to use thick pipe, vacuum capacitors, or devices that have no sliding contacts, such as butterfly capacitors where there are no moving parts (i.e., bearings) in the current path.

Receiving circuits? No such problem.

Unless it gets struck by lightning, then it won't just be the capacitor arcing..... :)

Nobody, but nobody makes crystal radios like Dave Schmarder makes crystal radios!!!

http://makearadio.com/crystal/index.php

and Dave's Loops:

http://makearadio.com/loops/index.php

You can't help but be impressed!

Wow, there are a lot of bad videos about making crystal radios on YouTube!

Steve Greenfield AE7HD

I've seen those but all of mine from 50 years ago were crude, no board mountings, first one had no tuner and received all 3 local stations and local hams so loud they would wake me in the mornings with the military headset under my bed. The later ones had a tapped coil and/or V-cap but not mountings, just wired together loosely. I even used a rusty nail and a corroded bronze penny as a detector, worked but poorly. I tried the last one on an 8" diameter (25 turn for 50') loop, worked but was weak. Somehow, I picked up a weak FM station, didn't know that could be done. My ground was a foot long bronze welding rod in the ground and I know better.

Let me see if i understand this: I have been looking hard at the loops Dave Schmarder makes and the circuit drawings. So, there is a multi-turn coil (loop) that gets tuned, and a secondary loop just built NEARBY that is somehow influenced by the first one?

I've got to find some wire. I went into a Radio Shack last week and they seem to be out of the wire biz. In fact, they seem to be more of a toy store. Not many real parts or pieces left. Back in 1983 I trained as a RS Company Store manager, went through the whole program and was a week away from taking a store when the job i really wanted in civil engineering came up. So, my wife and I packed up and moved to Wisconsin, leaving the RS store behind. At that time we had about a million discreet parts in the store and probably 30 or so kinds and sizes of wire. Thing of the past, i guess.

Can I use piano wire for loops? I have lots of that in the shop, just no copper. Piano wire comes in many gauges and a pound roll may have a half a mile of wire on it. Otherwise, it'll be "shop online" or find a motor I can canibalize. Over the past couple of years i have gutted a microwave and a big automatic shredder and some lights and have a little pile of parts, so i may have the right capacitor and perhaps I can cough up a variable without having to destroy something else. But, if I gut an old radio for parts it will be one less thing on the shelf in the storage room that my wife will have to tsk-tsk over when she walks by.

Piano wire has a lot more electrical resistance than copper,
and is not insulated and does not solder easily. That is
three strikes against it.

One of the best salvage sources of insulated copper wire for
loops is old color televisions and monitors. Most have a
large degaussing coil wrapped around the picture tube that
contains a significant amount of enameled copper wire.

If you can't lay your hands on some of those, and live in
the U.S., I can send you over a pound of 22AWG enameled wire
for about $10, shipped ($4 per pound plus my shipping cost).
It is from a big batch that spilled, so it is not on a
spool, but is just a loose but neat coil that may have a
slight tangle or two in it, but is pretty usable. I am
trying to find uses for it, rather than just recycle it.

Yes, many loop antennas use a coupled pick-up loop.

Radio Shack is indeed a phone and toy store these days, but you still can buy parts and wire there. Many fewer small parts, but they are there, usually in the pull-out shelves now. Wire, while not the cheapest, should be stocked too, in small spools on the walls. Insulated or enameled. You just need to find it.

Go to their website to find what you want, then walk in and look for/ask for those items. P/N 278-1345 is three small spools of enameled magnet wire, good enough for a small project or two.

Another source for lots of copper wire, are old fan motors, or any other motors. I've read you can also get free leftover wire from shops that rebuild electrical motors.

Sorry for the AWG typo. That is 20 AWG, heavy build, class H motor rated wire.

Hector,
I tried a google search of "40 meter delta loop" and got many hits. Here is one that looks easy to do and has a lot of info on the site:

http://w5sdc.net/delta_loop_for_hf.htm

There seems to be many variations on this antenna, I would look at as many different ones as you can find, and then pick one to try.

Best regards,

Pappy Hiram

English is not a first language for many people on this list. If someone seems rude to you, I suggest reading again and considering the possibility that the poster speaks English as a second language.

I know people who, despite English being their native language, still are misunderstood due to typos or poor word choices. I'm told that we Americans may be seen as rather abrupt and rude. So even if someone isn't from a "foreign" country (to someone in Brazil, -you- are in a foreign country), give them the benefit of the doubt.

So first, assume the best or at least don't assume the worst. If someone is truly being rude, it will become obvious in a few messages.

Keith asked, "Can I use piano wire for loops?"

I would use copper wire and got most of mine from a dead TV tube, lots of it, enameled, found some telephone cable with a dozen or more insulated wire in there and had to splice some together, all free for the asking. I made my small AM tuning loop with it, my tapped Xtal radio coil and others are for my office wall and ceiling single-turn loops for short wave listening.

Hear hear,
It was obvious by the grammar that Hector was not using his native language.
I wouldn't expect the flames from a "American" as the English language spoken and written is not unlike English originating in the UK. Moreover now, it is laced with Spanish
Yes I am aware that the language spoken in Brazil is Portuguese, but that often sounds and looks very similar to Spanish.
The flames appeared to come from this side of the pond from a person using a Dutch ISP. So there is a chance that the person who sent the flame was not reading his native language, and in his over exuberance for perfection has misguidedly assumed that all should reach the same degree of perfection.

There is one country in mainland Europe where level of exactitude and precision are considered to be the normality, however as one of our greatest scientists once said, in theory there is no difference between theory and practice, in practice there is.

In a few days I will unsubscribe from the list, it served its purpose when joining, when I required assistance on building Mag loops from coaxial hardline, but the need to stay on the list has passed.
Thanks for the previous help.

Funny you should mention TV tubes. I just gleaned a bunch of copper from a CRT yolk. ONly problem it was glued every so often making it a pain to take apart.

But I got LOTS of wire out of it.

Subject: [loopantennas] Wire for Loops

Keith asked, "Can I use piano wire for loops?"

I would use copper wire and got most of mine from a dead TV tube, lots of it, enameled, found some telephone cable with a dozen or more insulated wire in there and had to splice some together, all free for the asking. I made my small AM tuning loop with it, my tapped Xtal radio coil and others are for my office wall and ceiling single-turn loops for short wave listening.

7762. Loop Antenna in my Manhattan Condo

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-08-10 18:04:26 UTC
From: Monica Ann P
Topic: 7762 Message: 7762

Hi all. I have been following here for the last few weeks and I was wondering if I can get some feedback and hints on how I can better my antenna situation.

I recently got the ham bug again and I am trying to get my station on the air. I have an FT-950 which I love. I thought how can put up an antenna in my restricted space (I live on the fifth floor, facing east in Manhattan). My building is a large steel framed building with brick curtain walls. I don't have access to a balcony. I came across loop antennas and I thought to give it a shot.

My blog, http://kv2o.blogspot.com/, has a picture of my current setup. It is a rectangle, approximately 44" wide by 50" high consisting of 6 turns of #16 wire fed into a SGC-230 antenna tuner. The SGC-230 matches it well from 160m through 10m.

I haven't tried to make many QSOs yet, but I do get fairly good coverage and can hear DX and stateside stations, especially on 20m. W1AW is loud on 160m and 80m.

I was wondering if anyone has any tips or suggestions on what to improve.

It is possible for me to hand a wire down as a sort of vertical on the outside wall of the building, run a sort of dipole across all my windows (my apartment is 25' wide by 30' deep) and let the end droop and there is also a close by tree that I am thinking of throwing a thin wire across.

I don't think anything mounted in the apartment itself will radiate, since it is a big brick apartment house and 20 storeys high. I am on the fifth floor.

Any help or suggestions would be greatly appreciated.

Already taken care of.

I may have been a bit quick on the trigger... a search reveals that capntripps2000 has posted legitimately many times in the past. Normally I'd put someone on moderation until they fix the problem. I regret clicking the "ban" button so quickly, especially considering the history of the list that this one replaced and its moderator.

I've emailed Andrew about it and let him know that once he assures me the problem is fixed, he's welcome back.

I was going to suggest putting it on the glass. I've seen this before... Would it help to make it on a tripod mount in one room where you can turn it to optimize your direction?

The geeky part could be to add a microcontroller (arduino?) to motor control it from another room (shack)

Phil

Thanks so much for your suggestion.

I actually have a Tripod type of thing (actually its an octagon about 4ft across the points) that I have built for this very purpose. I have to add some supports this weekend and then I can mount he SGC-230 on it and rotate the direction of the loop as well as the location of the feedpoint (lower horizontal or vertical).

And I did think, if it works well, to include some rotator setup. For now though I will just turn it by hand until it is established that the refinement would be worthwhile.

English is not a first language for many people on this list. If someone seems rude to you, I suggest reading again and considering the possibility that the poster speaks English as a second language.

I know people who, despite English being their native language, still are misunderstood due to typos or poor word choices. I'm told that we Americans may be seen as rather abrupt and rude. So even if someone isn't from a "foreign" country (to someone in Brazil, -you- are in a foreign country), give them the benefit of the doubt.

So first, assume the best or at least don't assume the worst. If someone is truly being rude, it will become obvious in a few messages.

It's worth looking at the first part of the last paragraph of that page:

"Bearing in mind that most of the RF will be going skywards"

I've never understood why some people make horizontal full wave loops.
A horizontal full wave loop will beam half of the energy straight down
for a lot to be absorbed by ground resistance and the other half
straight up.
The MUF (http://www.spacew.com/www/realtime.php) has been increasing
lately, so I guess it's useful for local communication.

Hello Hector,

try Googling "40m delta loop".

Here is one page I found that looks good:
http://www.mccormick.uk.com/40%20meter%20loop/index.html

After reading this (and other pages), if you have some specific
questions, or things you do not understand, I am sure people in this
group can help you.

The ground will absorb some, but it will also reflect a great deal, particularly if the loop is at a suitable height, and the ground is of good conductivity.
The fact often missed with large horizontal loops is that they radiate vertically on their fundamental frequency, but as you change bands to use them on their harmonics, that angle of radiation changes to progressively lower angles, ultimately producing horizon kissing signals in the higher HF bands. Mike Holden G4HOL

The same is true of much of the energy from horizontal dipoles too,
just not to quite the same degree.

While some of the energy going down is lost, much of it is reflected
back up. This upward-going energy is what makes NVIS work, and gives
you local/regional coverage.

Some of the early work on NVIS actually used log-periodic antennas
that were aimed straight down, on purpose. Apparently they found they
worked better that way, using earth as a reflector, rather than
pointing up. Pointed either way, the beam interacts with the ground,
and I guess they found it worked better that way. (See the Fielder &
Farmer NVIS book, now out of print, for examples.)

As you go up in frequency, above foF2 (which is the MUF for NVIS), the
radiation from horizontal loops flattens out into more of a disk,
going more outwards than up or down. So the loop can be the best of
both worlds: an excellent NVIS antenna on lower frequencies that
support NVIS, morphing into a DX antenna on higher bands where NVIS
doesn't work.

Andy

Oh, we're full of it...I mean feedback and hints of course. :*)

> I recently got the ham bug again and I am trying to get my station on the air.

Excellent. I was first bitten 34+ years ago. Still haven't found the perfect antenna yet, but I'm still trying things. Need to order that spool of 2500 feet of Copperweld for the next antenna (No, I'm am NOT joking!).

> I have an FT-950 which I love.

Still using a Kenwood TS-820 here (complete with vacuum tubes in it, even!).

> I thought how can put up an antenna in my restricted space (I live on the fifth floor, facing east in Manhattan). My building is a large steel framed building with brick curtain walls. I don't have access to a balcony. I came across loop antennas and I thought to give it a shot.

Loops will work for you, but the problem may be that they can be VERY narrow banded. That may not be a problem for a CW signal, which occupies only a few Hz of bandwidth, but it may be a problem for a SSB signal, since the sidebands may fall far enough outside of the resonance frequency to be attenuated.

There have been quite a few designs over the years. Chris Trask, one of the members here, has written an excellent article about his work with loop antennas:

http://www.home.earthlink.net/~christrask/Transmitting%20Loop%20Antenna.pdf

There was quite a bit of interest in the DDRR (Directional Discontinuity Ring Radiator) antenna about 25-30 years ago (Ok, would you believe 40 years ago? Err, how about 50 years ago?), although I haven't heard much about it recently:

http://w9ttw.com/ddrr.htm

In any case, the basic problem is that a very short antenna (whether it's a dipole or a loop) is not going to couple energy to the outside world very well. Thus, you tend to have large voltages and currents flowing. In order to avoid excessive (I**2)*R "heating" losses, you need to hold the resistance down. That usually means heavy conductors, and capacitors which don't suffer resistance in moving joints.

There has also been some interest in using ferrite cored loop antennas, but it's awfully easy to overload the ferrite core and push it into magnetic saturation with very little transmitter power. I think a couple of the guys here may be working on things like that.

> My blog, http://kv2o.blogspot.com/, has a picture of my current setup. It is a rectangle, approximately 44" wide by 50" high consisting of 6 turns of #16 wire fed into a SGC-230 antenna tuner. The SGC-230 matches it well from 160m through 10m.

#16 gauge is probably about the minimum I'd consider for a transmitting loop. Note that some transmitting loop builders go as far as using Copper plumbing pipe for the loop, specifically to hold down the resistance.

> I haven't tried to make many QSOs yet, but I do get fairly good coverage and can hear DX and stateside stations, especially on 20m. W1AW is loud on 160m and 80m.

If it works, well, it works!

Be a little careful about making measurements from W1AW from your location, since they're just a few miles away in Newington, CT (which is east of you, too), and they have some rather fantastic antennas, too.

Can you hear WWV on any bands? That's in Ft. Collins, CO, which would be a bit better test (2.5 MHz, 5 MHz, 10 MHz, 15 MHz, and 20 MHz).

> I was wondering if anyone has any tips or suggestions on what to improve.

Use larger wire? I'd probably go with #12 gauge wire (Yes, I've stripped many hundreds of feet of NM electric wire to get at the individual conductors, although, in reality, this is soft drawn Copper wire, which makes for lousy suspended antennas, since it stretches under tension).

Make sure any capacitors in the loop circuit as able to handle the voltages and currents, and are low loss. Some loop builders use butterfly style capacitors so that there's no current flowing through a slip-connection (e.g., to the rotor plates) to hold down the resistance and losses.

> It is possible for me to hand a wire down as a sort of vertical on the outside wall of the building, run a sort of dipole across all my windows (my apartment is 25' wide by 30' deep) and let the end droop and there is also a close by tree that I am thinking of throwing a thin wire across.

You can droop a wire out the window, but you have to make sure that no one can reach it ("Hey, what's this wire outside my window? OWWWW!"). Trust me, RF burns HURT!

I've even occasionally resorted to using a Helium balloon to float a piece of magnet wire (I prefer #30 gauge.), although that doesn't really help, since you're not on the top floor. Plus, wind does bad things to Helium balloons. And, the Helium diffuses through the balloon walls quite rapidly, even if you use Hi-Float to make the envelope less permeable for the Helium.

The wire to the tree is a decent idea. Note that antennas tend to develop high voltages on the ends when transmitting, so it would probably be a good idea to stop the wire before it reaches the tree (lest it arc over to the tree and/or kill a branch).

You may want to look up the topic of "invisible antennas". A lot can be done with some light gauge magnet wire in conjunction with some monofilament fishing line. Of course, the UV in sunlight deteriorates the Nylon that the fishing line is made for, necessitating the replacement of it periodically.

Over all, though, think safety (both RF and electrical).

> I don't think anything mounted in the apartment itself will radiate, since it is a big brick apartment house and 20 storeys high. I am on the fifth floor.

One option may be to mount a mobile style antenna sticking out of a window. Those are usually pretty weak antennas, but they certainly will beat using a piece of wet spaghetti as an antenna. :*)

Dave

Thanks for all your thoughtful suggestions.

I do intend, in subsequent versions, to upgrade the wire to a heavier gauge.

I also want to try a copper tube version (luckily I can solder copper tubing well). I wonder if my SGC-230 can act as a tuning element for the copper loop?

I do hear some fairly good signals both stateside and DX so I think that at least on 40, I am functioning.

As to bandwidth, I like to operate CW most of all, so a narrow bandwidth antenna is a good match for me.

Using a tuner to tune a loop is very suboptimal. You should make
a ONE turn loop as big as you can (based on window) out of large
diameter copper and tune it with a high voltage capacitor. There
are commerical versions of this and many homebrew articles.
A small loop should be very narrow band, necessitating retuning
the capacitor after QSY. If not, it is indicative that the efficiency
is very low. Instead of actual copper tubing, you can run 3M copper
tape lengthwise along plastic pipe to fake it.

I worry that the window frame acts as a shorted turn.

I'm not sure where else you can put it, though. It depends heavily on what is in the walls - you might do better hanging it on an inside wall.

Thanks Steve

I worry about that too. I wish the window frames were wood, but they are not. I also worry cause the outside walls are brick, but it is curtain wall with some type of metal behind. Also some of the interior walls may have wire lathe behind the plaster.

Hmm, Maybe I can feed the aluminum frame as the loop itself!

I have a few option, but I think letting a wire go down vertically, a sort of inverted vertical, would be an option, but it would lie against the brick curtain wall. Same for a dipole I can string across a narrow window ledge.

This weekend I will try the wire thrown across the tree and see if the reception is an improvement. If it is, I may try to transmit at a low power.

I have lots of things to try, as well as a frame I built so I can try the loop inside the apartment a bit. Its basically a big octagon, about 48" across the points and on a mount 5 foot off the floor.

I would try the mult-iturn loop that SGC recommends on that frame and play with that.

I like experimenting and building, so this is fun to me. I am sure I will find something that works.

The point is, for the full wave loop, the emission is a double cone,
rather than a donut. with the dipole the action of the attenuated ground
reflection is to turn it into the (roughly) horizontal double cone and
hopefully to stations of interest.
With a horizontal full wave loop, most of the energy not lost the the
ground goes nearly straight up. With the sunspots as they have, the
energy will radiate out into space. If there are some ions up there, it
will come almost straight down again, so useful for local communications
only.

For a full wave loop, it makes much more sense to have it vertical. It
should still have gain over a dipole. Then you can add a director or
reflector or both (turning it into a quad) and pick up some more gain.

Hi,
Somewhere there are details of a ' super loop ', in the horizontal plane with three reflector wires laid on the ground below the antenna !!!!
I don't recall the author of the article.

Monica Ann--
With that tree there (if you can get a wire through the window) toss the weighted end of a wire out there, let some slide down, and load it as an inverted L with inverted feed !

If you chase DX, absolutely.

Me, I would use a full wave horizontal loop because I want local NVIS coverage for the people I need to talk to, and an antenna that optimizes DX misses that.

There seem to be lots of other people who like horizontal loops and may not be looking for NVIS. I guess it is either because it turns into a decent DX antenna when it is many wavelengths long, or because they are getting good performance out of it anyway at the lower frequencies that isn't strictly NVIS.

>> Some of the early work on NVIS actually used log-periodic antennas
>> that were aimed straight down, on purpose. ...
>>
> I wonder why they stopped doing that ;-)

Probably because it was a lot of hardware, just to get a very wideband antenna. (These people were researching the theory behind NVIS.) A more practical antenna might be a simple dipole, or something larger to get more gain; but not an upside-down LPDA which is so unwieldy.

Regards,
Andy

Hmmm... I've seen a couple of articles about a "super NVIS" antenna
which had a low dipole and three reflector wires laid on the ground.
(The authors were in or near Texas.) I haven't seen a version using a
horizontal loop. If you can find it, I'd love to see it. (I've been
thinking how one might do that.)

Andy,
You may be more correct than me in that it was a dipole with three reflector wires laid on the ground, old memory drives do strange things hi!
However, back in the late 90's I did add a reflector to my 40m full wave horizontal loop, the antenna was at 35ft in a diamond shape and the + 5% reflector loop at 15 ft, with 5 watts ssb I controlled a big inter G - EI net for hours on end, so it did work.
Strangely (another posting did mention this fact) on the odd occasion I could work nobody on the net, as though the radiated signal just kept on going hi!

Thanks Bill

So, I tried today, and heard an SP9 calling. He answered me after the second try and I was 57 on the loop. That was pretty sweet.

So now I know I am definitely able to transmit and I can use this as my baseline and improve from here.

I realized today that i have a spool of silver-plated copper wire in stock. It is pretty fine, the sort used to wind wire grips on violin bows. We usually use solid silver now, or German Silver, as the plated copper can give the player a green finger . Not good. But, it may be just the thing for an indoor loop.

So, it is solid conductor, not stranded. And it solders real well. If nothing else it would make a PRETTY loop.

Your comments are welcomed and sought. Thanks, keith

I've used loops mounted near windows with good results but for receive only. About a year or so ago I switched from magnet wire loops to one that uses a couple of turns of coax and it's a bit quieter on receive in my high RFI suburban environment. The shielded loop from coax is based on a design from Joe Carr's Receiving Antenna Handbook, but it's nothing unique - you can find similar designs for shielded loops all over the web.

For transmitting from your location, you might check into the Super Antenna MP-1. I'd been skeptical about loaded verticals but an acquaintance near the East Coast has used an MP-1 successfully to make contacts (voice on SSB running 100 watts or less) and I heard him many times last year from my home in Texas. I don't know how efficient it is, I can only say I heard him clearly several times in the 40m range.

Based on his experience the only drawbacks appear to be: the need for a counterpoise wire; and it's limited to fair weather operation - apparently it's very sensitive to precipitation; it needs to be mounted outside the building, but is small, lightweight and discrete enough that it could be rigged to work from a small temporary platform hung over an open window frame, or from a tripod on a balcony (I think you mentioned you don't have access to a balcony, though).

Many places in Manhattan will evict for merely being on the roof. That is part of my problem but the other part is metal window frames and bars compromise even a loop.

From: Monica Ann P
Topic: 7762 Message: 7792

Thanks everyone for there comments and input.

I got a few things accomplished this weekend. I built some shelves to put my equipment on, set up a 20m vertical hanging frommy window and got my old FT-707 up and running .

The big surprise was the 20m vertical. I cut it to length with two radials, tuned it using the MFJ analyzer and tried it side by side with the multi-turn loop. I tuned it with an old Ten-Tec tuner to an under 1:1.3 SWR.

No comparison. The vertical was loud and clear on signals that the loop didn't even hear. I am pretty happy with this so far.

Next experiment is to try a 40 meter vertical. Maybe next weekend!

Yes, indeed. The electrical conductivity is in the same range as
for iron and lead, depending on the alloy composition.

7796. Another loopamp built and working well with a small loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-08-17 01:33:42 UTC
From: Steve Ratzlaff
Topic: 7796 Message: 7796

I built the latest version of the Trask "A High Dynamic Range Amplifier for Wideband Active Loop Antennas" (8/3/2010 rev.) and initially had trouble with it, mainly with it being very noisy and covering up weak signals from a small loop. I set it aside until another list member who'd also built one told me his was noisy too and he'd traced it to VHF oscillations. It hadn't occurred to me to check for that but sure enough, mine was oscillating too, with a massive +17 dBm output. Primary oscillation was around 250 MHz with several other secondary oscillations (not harmonics), checked with a TEK 495P 1.8 GHz spectrum analyzer. I first tried ferrite beads on each transistor collector, but that didn't help at all. Leaving those in place I then put beads on each transistor base and that did the trick and killed all the oscillations. The amp is now quiet and I can probably remove the beads on the collectors though I haven't tried that yet. I tweaked the bias for about 97 mA at 13.0 volts supply; this seemed the highest I wanted to go since Q3,4 are already running very hot. 0.87 V on each emitter gives about 26 mA for each device; Q1,2 with 0.84 V for about 18 mA each device.
I ran some bench tests first. Using a 73-202 binoc core with 1:1 winding for 50 ohm unbalanced input/balanced output to the preamp loop inputs worked well. Gain at 1 MHz +23.6 dB; at 20 MHz (very broad minimum) +19.7 dB; at 40 MHz +23.5 dB. My primary spectrum analyzer, HP 3585A, stops at 40 MHz and I didn't try to check gain above that. Gain is mostly flat below 1 MHz, being -3 dB down at 47 kHz and -6 dB down at 13 kHz referred to gain at 1 MHz. (I used 1 uF monolithic caps for C2,3.)
For two-tone IMD tests I used my standard setup of 3 and 4 MHz test tones, set for 0 dBm at the output of the preamp to the spectrum analyzer. I used a 3/4 MHz band reject filter with a 20 db pad in front of the filter that effectively removes both fundamentals and allows the SA to operate at full sensitivity at the IMD frequencies without being overloaded by the very strong test tones. I checked IMD at 1, 2, 5, 7 MHz.
IMD results with 13.0 volts supply:
1 MHz +91.5 OIP2
2 MHz +45.2 OIP3
5 MHz +43.3 OIP3
7 MHz +94 OIP2
These indicate pretty decent results which should give good resistance to overload and also indicate that my circuit current is probably close to optimum.

I've been doing various small loop and associated loopamp tests the past several months; I made a 6 foot square PVC frame that I hang loops on for testing, and can check a loopamp as well. I have been interested in testing "crossed-parallel" loops, mentioned in the in the LZ1AQ article on his webpage (and also interested in building and testing his loopamp). I had built four 38 inch diameter single-turn loops of 1/2 inch soft copper tubing and compared them, connected quad cross-parallel (CP) configuration, to a

single-turn loop using 19 foot circumference 1/2 inch soft copper tubing (about 6 feet 4 inches diameter). The combined area of the quad small loops is just a little greater than the larger single loop area, and should give similar signal levels to a loopamp. (Actually, LZ1AQ seems to indicate that the quad CP loops should work better than a single larger area loop.) I have a whole range of weak signals (and some strong signals) on frequencies from 19.8 kHz to 20 MHz that I check each loop and loopamp for signal level, using an AOR AR-7030 receiver which has a very accurate digital bargraph S meter as the measuring instrument. I primarily use the 6 foot loop for preamp checks. So far my best homebrew loopamp has been the M0AYF preamp modified with trifilar output transformer. This has the most gain (+34 dB at 1 MHz) and hears the various weak signals the best, though its IMD results from bench testing are only moderate. I live in a rural area with low AC noise level and no nearby strong stations such as strong AMBC stations, so I can readily do comparisons among loops and loopamps of weak signals over a wide frequency range. I was not expecting a lot for the Trask loopamp with its approximately 10 dB less gain. But it's a quiet amp; and that's why it's fun to build, test and compare things such as loops and loopamps, to see how one compares to another. I was pleasantly surprised--even though the results showed it was 1-2 S units lower output than the M0AYF loopamp, every signal could be heard with about the same S/N ratio, over the whole frequency range from 19.8 kHz to 20 MHz (WWV time signal).

I built my loopamp using 43-303 binoc cores for all 6 main transformers; I left out L1, L2 and associated components on the input and ran the loop directly to C2,3. I matched the Q1,2 and Q3,4 transistor pairs for beta as close as I could with my limited supply of MPS6521s--my emitter voltages turned out to be equal for Q1,2 and Q3,4, so it must have been fairly close matching. As I do with all the loopamps I've been testing, I powered this loopamp separately with a small 12 volt gelcell outside at the loopamp, not powered down the coax cable as would be done for normal remote-loop and loopamp operation. I wound T6 slightly different from the article's Fig. 9 picture (and T3 as well). It does appear that ferrite beads (I used short beads,#43 material) need to be added to each transistor base as close to the transistor as possible, to suppress VHF oscillations. The bias needs to be adjustable; at least on mine--using just the original 68 ohm resistor gave only about 50 mA total initial circuit current for the particular devices I used.
After getting the oscillations tamed, this loopamp compares very favorably with my other best homebrew loopamps (not all of them worked well like this one eventually did). I give it a thumbs up!
73,
Steve

Steve,
Nice work. I'm surprised at the oscillation problem as I did not have any trouble in that regard. I'm going to be building another version that should have better than +50dBm OIP3 and I'll see if I can force it and the original one to oscillate. Very often a small resistor in series with the collector lead can kill the VHF problem, but I'll try ferrite beads on the base leads first.

I'm using a 16:1 UnBal between the 50-ohm generator(s) and the amplifier input, wound just like T4 on a 43 core instead of 61. That low source impedance may be why I didn't experience any oscillations.

Chris

Dear Steve

great stuff, very detailed work you have on Chris's design

I wish I knew 10% of what you guys know and can do
amazing work all around

I take it little ferrite beads on all the base lead are more or less mandatory

best wishes
Paul VE3PVB

7799. sources for variable capacitors???

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-08-19 15:33:07 UTC
From: kg6wla
Topic: 7799 Message: 7799

Hi everyone,
I am planning on building my first small transmitting loop and I am having trouble locating suppliers for variable capacitors. I recall that ocean state electronics had some in the past, but it seems they are out of business now.
I found a couple other companies with a quick google search... Who do you like to deal with?

From the specs Im looking at, I need to find a cap able to handle about 5kv RMS, with a range between 14-pF - 65pF. My goal is to work the 20-10 meter bands.

I used the loop calculator on this site:
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx

RESULTS:
Antenna efficiency: 59% (-2.3 dB below 100%)
Antenna bandwidth: 13.2 kHz
Tuning Capacitance: 65pF

Capacitor voltage: 4,290 volts RMS
Resonant circulating current: 24.7 A
Radiation resistance: 0.048 ohms
Loss Resistance: 0.034 ohms
Inductance: 1.98 microhenrys
Inductive Reactance: 174 ohms
Quality Factor (Q): 1,059
Distributed capacity: 7 pF

Antenna "circumference": 9 feet
Loop dimensions Side length: 1.13 feet
Antenna diameter: 2.7 feet

Comments:
The specified conductor length of 9 feet is OK.

Conductor length should be between 8.52 and 17.0 feet at the specified frequency of 14 MHz.

For highest efficiency, the conductor length for a small transmitting loop antenna should be greater than 1/8 wavelength (greater than about 8.52 feet at the specified frequency of 14 MHz).

To avoid self-resonance, the conductor length for a small transmitting loop antenna should be less than 1/4 wavelength (less than about 17.0 feet at the specified frequency of 14 MHz).

Input Values:
Length of conductor: 9 feet
Diameter of conductor: 1 inches

Frequency: 14 MHz
Transmitter power: 100 watts

THANKS,
Ryan

7800. Re: sources for variable capacitors???

Yahoo group: loopantennas (2008 — 2012)

From: bm40g
Topic: 7799 Message: 7800

Hi Ryan,

The length of the element needs to be less than 1/2, not 1/4 to avoid self resonance. My transmitting loop is 4 foot 6 inches in diameter, which is 14.1 foot (4.3 meters) in circumference. 1/2 wavelength would be just above ten meters, 1/4 wavelength 17 meters, and the antenna is working just fine on 18 MHz.

So, do not be afraid to make the loop longer, it wont be a magnetic loop above 1/4 wavelength, but, it will work just fine. And the longer length will reduced the capacitor requirements.

My first capacitor was a butterfly cap in my junk-box. But the second was a hamfest find earlier this year. I have just recently installed it. Its a split stator cap - 1 1/2 foot long, and 6" by 6" when at min capacitance.

Take a look at this link: http://www.aa3mw.com/antenna_parts/ . I was about to contact him before finding the cap I did.

Thick wall plumbing copper in 3/4 size is .9 inches OD, available in 10ft sticks with 45 elbows at amy home store.

Try increasing to 16ft, 2 ft per side with the octagional design the calculator uses.

This drops voltage and current to 3.3Kv at 9.5 amps or less and increases to 85% efficiency and 45khz B/W.

Loop is still only 4.8 feet across and you have more room for the cap assembly.

If using fixed freq google for "trombone capaciter" Easily made from copper tube and coax, or 2 sizes of tube and some sched 40 PVC.

For tunable, MFJ and a few others sell the same caps they use in AMPS and tuners as parts. A butterfly type rated at 5KV and covering 25 - 150 pf would be perfect for covering 40, 30, 20 meters, and could easily be remote tuned with a gear reduction motor.

Also, vacume variable types are avail, check Max Gain Systems as a start.

For remoting though, you would need a gear reduction motor with _stops_.

- Sched 40 PVC would be a terrible choice for a high-voltage capacitor dielectric used in a transmitting loop variable capacitor. A trombone-type fixed or variable capacitor can be an excellent choice for a transmitting loop but only
if the correct dielectric is used. Using coax itself is also a very lossy choice
for a capacitor.

I would recommend using only Teflon sheet or as a second choice
polyethylene sheet for an insulator of a trombone-style capacitor.
The plastic sheeting is wrapped tightly around the
inner pipe of the trombone capacitor and secured in place with Teflon-type tape.
Also the builder needs to
understand the thickness of the insulating plastic needed to survive the high-voltage developed in a transmitting loop and the builder needs to understand the capacitance related to the spacing between the pipes and the length of the pipes.

An excellent article on building a home made trombone capacitor for a transmitting loop is the article by Bill Jones KD7S in the November, 1994 issue of QST magazine titled " A Homebrew Loop Tuning Capacitor".

Building your own loop tuning capacitor can save a lot of money compared to buying a vacuum variable but it requires knowledge of using the best materials available. Using a lossy capacitor is probably the most common mistake most loop builders make. Making a good transmitting loop requires the builder know how to make and use a good quality capacitor, plus use
only the best connections between the capacitor and the loop. A trombone capacitor can be soldered directly to the loop.

Thanks for the information everyone. I am really excited to get started with the project. My last antenna project was a 2m square loop for weak signal work, so when I found out about the potential of a small multiband antenna for HF I was very pleased.
I guess I will be going with with a circumference greater than 9 feet as some have recommended. My plans are to use a vacuum capacitor (if found at a low cost) but more likely, a standard variable capacitor with a motor/gear drive.

Thanks for giving me some places to look for variable capacitors! :)

From: bm40g
Topic: 7805 Message: 7805

Hi All,

I have added some pictures of my loop antenna (version 2 - its already rebuilt into version 3 now with the big cap, but no pictures of that yet) and the big split stator capacitor I have replaced the butterfly cap with.

7806. Re: sources for variable capacitors???

Building my own is something I am considering, and I could use the experience! I just don't know about that eham article mentioned earlier, I guess I could substitute the roof flashing with something more substantial.
Thank

Ryan :)

Thanks Danny,

You have not seen Version 3 yet! It looks much less rube-goldberg than version 2, and if I bump into it in the living room, it does not detune, like version 2.

Worked a station today in Rusia in at the NE tip of China with it. Also, France and Uruquay on the 17 meter band.

I have never built variable capacitors but I have looked into it.

As I think you're saying, in reference to construction articles, flashing is flimsy, and may be hard to keep flat.

If you don't know where to get metal sheet locally, one online supplier for small quantities of metal sheet, which I have looked at (though I haven't used them yet) is http://www.onlinemetals.com/ .

If anyone is serious about building these things, maybe we could enhance existing published designs by making up some gcode for CNC to cut out the plates and maybe the plexiglass supports.

For anyone interested in building their own high-voltage, low-loss variable
capacitor
for a transmitting loop I highly recommend the article by Bill Jones, KD7S
titled
"A Homebrew Loop Tuning Capacitor". His article appeared in the Nov, 1994
issue
of QST magazine and it is still the best article I have ever seen published
on the subject.

Bill gives step by step directions with detailed drawings on how to build a
trombone-style
variable tuning capacitor with remote motor drive for a transmitting loop.
There are many
advantages to building a trombone-style tuning capacitor:

Uses common copper pipe for the elements, no flimsy copper sheets or
flashing.
No need for tedious cutting of many sheets of copper for capacitor plates
or critical spacing
The copper pipe is very rigid = Frequency-stable for precision tuning.
Uses common 12VDC gear motor or can use a stepper motor for tuning
Simple to build motor drive uses a threaded rod and brass knurled nut.
Uses Teflon sheet for insulation. Lowest loss, Easy to use, capacitor stays
aligned
The copper pipe capacitor can be incorporated directly into the
transmitting loop for lowest loss

If a few folks are interested in the article and are not members of the ARRL write to me
and I will send you a pdf copy of the article.

Re: CNC code
Yes! I agree. You may find somewhere that can CNC or laser cut for you for a reasonable charge. There is a place in Seattle, WA where you can go in and work on projects, I think they have a CNC they rent time on.

I have a small kit CNC machine I'm still working on, slowly. Have the driver board nearly completed, and just picked up a suitable power supply at a hamfest.

It should be suitable for cutting copper, which is really the only choice if you are shooting for a low loss butterfly capacitor.

Actually, my brother was a CNC button jockey at a local machine shop. I will see if he can talk to his former boss about either using the equipment or the costs of such a job. In this area machine work has been a little light, so the equipment may be available for a small project like this.

Here are a couple of pages with drawings for butterfly capacitor rotors, stators and end plates.

http://fucimin.altervista.org/en/loop.html

http://www.qsl.net/m/mnqrp//Loop/Mag_Loops.htm

Trombone looks interesting, but maybe not as compact as a rotary butterfly capacitor. The qsl.net page has a drawing of a "piston" capacitor. Is that the same as "trombone"?

The two butterfly designs look pretty much identical. You will get 5 ☐ 56pF with 5 rotors and 6 stators. It scales up from there with more elements. Is this a good size to make?

I am pretty sure a lot of people use aluminum for these designs. I think, particularly for rotors since they don't have to connect to anything but only capacitively couple, aluminum would be OK. Maybe copper would be better for the stators, if it will end up making a better connection with the rods.

I looked at the first link and I can see many problems with the butterfly
capacitor
as shown. First problem I see is you should never mix aluminum with brass
hardware. The dissimilar metals will quickly develop galvanic corrosion and
develop
poor contact at the joints.

For a transmitting loop the plates of a capacitor should be soldered or
brazed to the
rotor or stator. A capacitor using plates that are only pressed together or
held together with threaded
hardware is too lossy for transmitting loop use. Plus aluminum plates
cannot be easily soldered to brass which is another reason not to use
dissimilar metals.

The butterfly capacitors in the second link look like they show the same
problems
mixing aluminum plates with brass hardware.

None of these problems occur with a soldered copper-pipe trombone-style
capacitor. The terms
Trombone Capacitor and Piston Capacitor mean the same thing in the
different
articles I have read.

Have a look at this web site Ryan --- www.MonarchCapacitors.com.It is a new site being setup to distribute TX Loop Cap kits now sold over Ebay. The current site has a calculator to assist you in determining the number of plates you will require to achieve the desired capacitance.

There is also a new Yahoo Group site focused on Transmitting loops for Hams, look in the Yahoo Group directory for "MagLoops". You should be able to get more info there as well.

Hope this helps!

I fully appreciate ones desire to "roll " your own. No questions about that.
However, it seems counmterproductive to build relatively inexpensive tx
loop from cooper tubing and than compromise the design by building variable
capacitor of dubious quality - dissimilar metals, press fit

construction, flimsy aluminum plates.
My chiose is real vacuum variable capacitor.
So, back to the original post
- source is well known web market place.

Vaclav,
My intention was not to build my own this early into my loop experiments... It is one of those things I would like to try. As for caps, I really do like the advantages of the vac. caps. Its just the cost... some of them are quite expensive. I have been looking on the max-gain systems webpage. They seem to have quite the selection.

Please take a look at the famous auction site. Good used vacuum capacitors appear from time to time in strange categories, and can be quite cheap. The sellers loss is your gain. I have purchased two with capacities of up to 100 pf for 25-30 US bucks. They arrived in fine shape and are in use here.

Hi Chris,

I'm getting ready to put together your Wideband Loop Amp. Before I start winding and soldering, I have a couple of questions:

If I use type 73 material for the transformer cores (my interest is NDB DXing), should I adjust the turns count, or stick with what's specified in your document?

For the case of the Q6 JFET, I have no 2N/PN4416 device on hand, but do have several other types. In selecting an alternative, am I correct in thinking that a low goss (output conductance) spec should correlate to a "flatter" drain current curve beyond the transition region?

Thanks again for taking the time to publish your work -- its greatly appreciated.

Since your interest is in lower frequencies, I'd say yes to increasing the number of turns. You can get as many as six turns of #32 trifilar in the 2402 augmentation transformer cores (T1, T2, T4, and T5). And then go to eight turns on T3 and T6 for good measure.

You may want to add a low ESR 1uF electrolytic in parallel with C2 and C3 to ensure good coupling at the lower frequencies.

Let's see what you have available. A J309 can be used, but you'll need to adjust R6 to get the desired current.

>

I have a small change in the works that will improve the gain by 6dB without adding any parts or changing the supply current. That will be included later when I complete the +50dBm OIP3 version.

Like Howard Cossell used to say: "We keep making it better, not more expensive."

I should have mentioned to add a ferrite bead to the base leads of all four transistors to prevent VHF oscillations.

Thanks Chris,

The FETs I have on hand for Q6 are the J113, J304, 2N4393, and a bunch of 2N3819s. Also just found an NTE 312, which is supposed to be the NTE replacement part for the PN4416. I'll put socket pins in the board so I can try different ones. I'll definitely have a pot for R6.

Looking forward to seeing your improved version.

Hi Chris
I wrote to you via the link at the right of the message but haven't get any reply from you. I suppose your connection is blocked? Anyway, I just would like to know if an adjustable telescopic antenna like those that are used on car (electric) could be used with an preamp for 100kHz up to about 1.8 mHz, my main band interest. Here, we have only one local AM broadcast station located at about 15 miles away with a power of 50kW. Of course, night reception bring a lot of powerful station from the US. Why use an electric telescoping antenna? To adjust the gain, I used to use AM car radio and found that the more I extend the antenna, the more I get gain. Any suggestion for me? Thanks
Danny

Hi Danny,

Interestingly, an old car radio is the best receiver to use with a short whip. Its input is already designed for such kind of antenna, and you can get it for close to free. And it works great if you are far from electrical noise.
However, if you want to reduce noise or to null out one station to listen to another on the same frequency, you need a loop.
My opinion is that tuned loop is better for DX listening on MW band. As a bonus, you can reduce the gain by detuning.
A broadband loop or a whip is a must for SDR which looks at a big chunk of spectrum.

Hi Mike. I agree with you but I've noticed that recent digital car radio has excellent sensitivity and selectivity. The latest I've tried are original car radio from an corolla 1997 and an echo 2005. Both have surprised me in both sensitivity and selectivity but they suffered from adjacent channel rejection. I tried a 102 inch CB antenna on the 1997 model and the results were amazing. I also tried to put a 230 mH coil in between the antenna and it's base. Even if I was in a no noise location, the noise increased, especially on the higher part of the AM band.

> However, if you want to reduce noise or to null out one station to listen to another on the same frequency, you need a loop.
> My opinion is that tuned loop is better for DX listening on MW band. As a bonus, you can reduce the gain by detuning.

I used to use loop antenna in my house with great results. I also tried ferrite antenna with pre-amp and results were very good.

Software Defined Radio.
Some SDR receivers can record the whole MW band at once for later analysis.

7834. Indoor ceiling loop antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-09-01 16:53:36 UTC
From: mojavedxer
Topic: 7834 Message: 7834

I am planning to redo my current makeshift indoor antenna to something more permanent.

1. If I run a wire around the perimeter of the radio room in a loop configuration. Will multiple turns help lower the resonance of the antenna or is it a waste of time, I am planning to use a 1" space between the turns.

2. What would be the best way to connect a coax feed line in a loop configuration. 9/1 un/un or 4/1 balun.

3. Would a antenna tuner be beneficial in this case. This antenna would be used for reception only,

4. since grounding is not available. Would creating two 20' radials running against the baseboards of the radio room help lower the noise level.

More turns increases the total inductance and electrical length of the loop. Both effect5s lower the self resonant frequency. Increased space between the turns lowers the the turn-to-turn capacitance and also lowers the loop inductance. Both effects raise the self resonant frequency of the loop.

> 2. What would be the best way to connect a coax feed line
> in a loop configuration. 9/1 un/un or 4/1 balun.

You might consider a transformer coupling made with a ferrite bead. This works best if the loop tuning is on the loop side of the transformer.

> 3. Would a antenna tuner be beneficial in this case. This
> antenna would be used for reception only,

Resonating the antenna at the received frequency will not only increase the signal strength at that frequency, it will lower the signal strength of frequencies on each side of that frequency, decreasing interference.

> 4. since grounding is not available. Would creating two
> 20' radials running against the baseboards of the radio
> room help lower the noise level.

A loop antenna much shorter than a half wavelength does not generally benefit much from ground planes or ground connections. There need be only a ground connection at the receiver to carry away static charge.

Keep in mind that a horizontal loop has maximum sensitivity for propagation that has a vertical magnetic component (that passes parallel to the axis of the loop). But this is not a common or efficient mode for most radio wave broadcasts, because that puts the E field component parallel to the ground, where is is most absorbed by the soil. I think you would be better served by circling a wall with the loop,

though you may need to make two loops, one on each wall meeting at a corner, and switch between them, depending on the direction to the transmitter. There is no loop configuration that has the omni directional pattern of a vertical whip, E-field antenna. this is both a benefit (to null a strong interfering signal) and a detriment (can't use a single, fixed loop to receive from any direction).

7836. PVC Loop Suggestions and Advise for the Tecsun PL-390

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-09-04 09:14:27 UTC
From: ed_plopenio
Topic: 7836 Message: 7836

Hi everybody. This is my first post after a few months of reading and learning for the group

I would like to build a recieve only MW loop from magnetic wire and a recieve only coax cable SW shielded loop antenna using the same PVC frame. What would be the width and height of the collapsible/portable PVC frame? How many turns of magnetic wire and the spacing between turns for the MW loop? I am assuming that the SW coax would have only 1 turn. I imagine also that both loops can have a common connection to the ground terminal of the 3.5 mm socket with the MW connected to the socket's middle terminal and the SW connectcted to the tip's terminal. I plan to use thses antennas on a Tecsun PL-390 which is on order. Is it possible that both the MW and SW antennas to have an inductance between 10 and 20 uH using a 1:5 turn ratio following the Si4734 DSP chip specs so that both antennas can be tuned directly with the modified PL-390 describe here

(http://f1.grp.yahoofs.com/v1/ELmATP_lM160pzEINc06OhFQCLxtBEPdEKGPXU1pJo8oqgEIcSd2ZN6fdSGe42olHclNp8H-x8u_jPYJGioj-s3FK8IJ823EPgI/6%20Alignment%20%26%20Modification/PL-390%20External%20LW%20MW%20Antenna%20Mod.pdf)

What is a 1:5 turn ratio inductor and how do I make one?

Also, would it be possible to improve the PL-390's ferrite loopstick sensitivity by either replacing it with one of better quality and/or by rewinding the litz wire. I have read about a 3-coil design by Hugo described at the Herculodge website

(http://herculodge.typepad.com/herculodge/2010/03/is-it-true-the-saying-that-the-bigger-the-ferrite-the-better-am-sensitivity-.html)

or his more recent post

(http://herculodge.typepad.com/herculodge/2010/09/hugo-shows-the-best-way-to-maximize-performance-on-your-ferrite-antenna.html)?

I believe the Tecsun PL-390 can turn out to be a "Super DX" portable radio with Mr. Mann's modification, a collapsible/portable common framed MW & SW PVC Loop antenna and a modified ferrite loopstick,

Many thanks for any and all comments, suggestions and advise.

Ed Plopenio

Hi Ed;

Welcome to the world of radio. I will address a portion of your post ... the internal ferrite of the PL-390 and external loop - and also caution you to ask many many questions before you think you fully understand, because there is much to learn and many opinions on what and will not work. And please be aware you are asking "experimenter questions" ... questions which maybe only you can answer after you have tried :)

That said, I wonder in what order you want to make these modifications and antennas? You have outlined an ambitious amount of work!

Whether mounting a MW multi-turn open loop alongside a coax single turn loop is a good or bad idea - I don't know. My gut instinct says you may have interference problems between the two antennas windings ... capacitive and possibly inductive too. Good question and hoping someone else has tried it and can comment. However, I know that making both an external multi-turn open MW loop AND modifying the internal ferrite with Litz wire seems counter-productive. If you are going to make a pickup loop mounted to your multi-turn and direct-connect that to the PL-390, what is the purpose of the Litz re-wire of the ferrite? If you are going to inductively couple the multi-turn loop to the PL-390, the internal ferrite will work great just as it is. I doubt you would see much performance gain by re-winding the ferrite for this application. If you are itching to wind Litz wire on a ferrite, I would suggest investing in a long ferrite rod and winding an external tunable "super-ferrite". You can always cascade the super-ferrite and the multi-turn loop together with inductive coupling and you will achieve extra signal gain plus the ability to play one antennas' nulls against the other for some amazing daytime DX. A tried and proven way to achieve MW & SW on one frame is to use tap points on a open multi-turn winding, making the open winding anything from one to several turns, depending on your tap point. Whether the shielded coax will give you better noise reduction over an open single turn magnet wire has been debated. It's output will probably be lower.

Please report back if you try some of these ideas. Let us know how things worked or didn't work.

Mark

Hi
I have a number of external active loop antennas. The instructions that
came with a couple of the antennas say thatpower to the antenna should
be maintained 24/7 apparently to maintain slight heat within thepre amp
at all times. The others make no mention of this.
So with winter approaching should I keep the power on all the time ?
will this shorten the antenna life ?
Regards to all

Hi Jason - I'm not sure why they would specify that power be maintained unless the slight heating inside the case is enough to deter any condensation from building up. Running the preamp 24/7 will not harm anything whatsoever. When operated within their ratings, transistors and most solid state components should have an operating life in the 'hundreds' of years!

7842. Shielded Loop preamp suggestions?

Yahoo group: loopantennas (2008 — 2012)

From: w9ran
Topic: 7842 Message: 7842

My Wellbrook shielded loop bit the dust last year, and I'd like to put it back in service. Primary interest is in LW and BC band DX-ing. I've been looking thru the archives as well as other sources, but would appreciate any suggestions. This is an untuned loop, a broadband preamp would be fine if it's reasonably immune to cross modulation, otherwise a cutoff at 2-3 mhz would be OK. Simple is better than complex.

Thanks and 73,
Bob W9RAN

Hello Bob,
Maybe the best thing to do is to approach Andy Ikin of Wellbrook First. He may be helpful in repair or replacement.

If you want to build something yourself, take a look at these.

http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna.htm

http://groups.yahoo.com/group/loopantennas/files/Wideband%20Loop%20Antenna%20Amplifier.pdf

http://www.qrss.thersgb.net/active-loop-receiving-antenna.html

There has been a recent discussion on them, you can find that in the message archive.

I believe all three designers of these active broadband loops are members of this Group.

regards,

Cor Beijersbergen

Bob, have a look at the new Pixel Loop ---

http://store.xmfanstore.com/pixel-technologies-magnetic-loop-antenna-pro-1.html

It is available in the States since it is made here.

I have one and it's very well made. No parts are potted therefore it is repairable.

Cheers!
Lloyd

A couple of general comments on preamps.
The amount of preamp gain you need is to
be about 6 dB more than the sum of
the receiver noise figure and the feedline
loss. You don't want more gain than necessary
because it just reduces the dynamic range.
30 dB of gain is way too way IMHO, unless your
receiver is dead or you have a mile of feedline.
The OIP3 of +46 dBm sounds impressive until
you realize that this is only +16 dBm at
the input, after accounting for the 30 dB of
gain. No matter how much gain the preamp has,
the sensitivity will be limited by the room
temperature thermal noise of the 50 ohm swamping
resistor. It is trivial to get a 1 dB NF,
which will be within 1 dB of the best you will
do with an untuned 38 inch loop. It is completely
unjustified IMHO to charge four Benjamins for a
preamp that could be equaled by a <$4 IC. See
Mini-Circuits for examples.

72 feet of #12 stranded copper wire at a hardware store is a lot cheaper and makes a great receiving loop (18 feet square) that will work great from 500 Khz to 30 MHZ without a preamp and will fit in most back yards , (about 20 bucks or a little less)

i would kick myself in the pants for spending 400 bucks on that

DISCLAIMER: i am not trying to sound mean, just being practical.

At that size, it isn't really going to work like the classic loop
above 5 or 10 MHz. It will have a funky pattern above 14 MHz where
it is a full wavelength. But you will probably not need a preamp
in most cases.

since it is for receive only you wont have to worry about a pattern, thats for TX, not RX, i have one right now in a horizontal loop and dont have a problem with it (works great on all bands)

the only time a pattern comes in to play for receive is with highly directional antennas like a log periodic or yagi

You can make the same loop for less than $100 using my amplifier and the
guidelines in the paper "Mastering the Art of the Shielded Loop Antenna",
both of which are in the list files section.

Hello Rick

The reason for the significant gain is there is an enormous mismatch
between the antenna and the amplifier.

The radiation resistance of a small single turn loop (from Jasik, Antenna
Enginneering Handbook,1st ed) is:
19,000 (D / lambda) ^4
So at 1 MHz, a 1 meter diameter loop will have a radiation resistance of
2.3 micro-ohms. The resistance of the loop will be much larger than this, and
the amplifier input impedance will be a small number of ohms.

The Pixel Technologies spec sheet does not give the antenna factor or the
frequency response for their loop, but 30 dB is "about right" for an antenna
factor of ca. 0.5 to 1.0.

The radiation resistance is irrelevant because, as you say,
it is dominated by the ohmic resistance of the loop. In an
UNTUNED broadband loop, the ohmic resistance is also irrelevant,
because it is dominated by the inductance of the loop, which
is not tuned out.

You seem to be saying that if the antenna has a gain of -30
dBi, the preamp should have a gain of +30 dBi, as if there
were a rule that the signal strength at the receiver must
be the same as an isotropic antenna. There is no such
rule.

The only requirement is for the noise of the preamp to dominate
the receiver noise. For example, my FT-1000 has a noise figure
of 12 dB. If I put an 18 dB preamp in front of it, the NF
of the system will be about 1 dB worse than the NF of the preamp
alone. IE, if the preamp has 2 dB NF, the resulting system will
have a 3 dB NF. It is irrelevant whether the antenna gain is
-10 dBi, -30 dBi, or -50 dBi, etc.

All of this can be avoided by using a remote varactor tuned loop.
The output signal is so much higher that you don't need a preamp.

Chris, thanks for posting the reference; that and your paper on your amplifier are just what I was looking for.

In fact, I have been slowing reading my through the various papers you have put on your website. Their level of technical detail I find challenging and informative, what better way to improve my level of understanding of the various subject matter.

Cheers, Graham ve3gtc / ve3ghm (mostly QRP CW and digital modes and a constant tinkerer)

You can make the same loop for less than $100 using my amplifier and
the
guidelines in the paper "Mastering the Art of the Shielded Loop
Antenna",
both of which are in the list files section.

I thought the shielded loop and loop amplifier papers might be useful to you. With those, you can make your own antenna that will have performace on a par with that of the Welbrook and Pixel products but costing far less.

I have the parts for making an even better amplifier, but I'm tied up with the design of a low IMD mixer at the moment.

Two EL2125C's in a fully differential configuration. I've used a gain of up to 46 dB. They are the absolute lowest noise op amp available anywhere and have plenty of bandwidth when operated from +/-5V.

> My Wellbrook shielded loop bit the dust last year, and I'd like to put it back in service. Primary interest is in LW and BC band DX-ing. I've been looking thru the archives as well as other sources, but would appreciate any suggestions. This is an untuned loop, a broadband preamp would be fine if it's reasonably immune to cross modulation, otherwise a cutoff at 2-3 mhz would be OK. Simple is better than complex.

I am not saying that if the antenna has a gain of -30dB, then the amplifier should have a gain of +30dB.

One reference which I find very useful is:
B.M. Sosin, H.F. Active Antenna performance requirements and realization, Communications and Broadcasting, Summer 1976, pp 29-34.

Sosin's approach is to consider the atmospheric noise level and receiver noise factor, and use these to detemine the required active antenna gain for a 3dB increase in receiver noise. He defines the active antenna gain as the output of the active antenna divided by that of a matched short vertical antenna.

Sosin calculates a required active antenna gain at 10MHz of -20dB, with a comment that it might be desirable to increase this by 3 to 8 dB if it were desired to avoid the noise deterioration.

It is then relatively straightforward to calculate a required antenna factor for this gain. The required gain of the antenna amplifier then depends upon the loop area, and the amplifier input impedance.

I posted some loop antenna calculations to this group back in May 2007.

Hi Bruce,
Can you please post the diagram of your amplifier?
I've got two EL2125C as free samples from Intersil.
I'm playing with a simple inverting configuration with 1k feedback resistor. My problem is the input part, namely the common-mode suppression transformer. I lack the knowledge necessary to optimize this thing.
The amplifier works just fine without the transformer, but I suspect it just picks up the common mode (it keeps receiving when I disconnect the "cold" side of the loop). With my 1:1 transformer and a 1m dia. loop the sensitivity is pathetic.

As for the differential configuration, wouldn't it increase the noise by 3dB? The gain by itself is not that interesting when loop is the input, you need to measure the total system gain as the ratio of output in uV to input in uV/m.

73,
Mike

IMHO: Looks like ham radio with the gamma match at the bottom and a small coax partially hidden - RG-174? Most of the loop is at ground. Not good for MW. Also
too small for MW - 6in??? 224mHz? 1.2gHz? For MW a small (3ft) metal tube loop would need an amp.

A mobius strip loop antenna is a loop made with a single turn loop mad of coax,
with the center conductor and shield interconnected so that it acts like
a two turn loop. That's the characteristic referred to in the ad for
the Pixel PRO-1A
antenna. Here's a link to the publication by Dr. Baum explaining the
operation.
http://ece.unm.edu/summa/notes/SSN/note7.pdf

Named after the mobius strip which is a geometric shape
with only one surface.

As I mentioned in an earlier private email, I have had one of these for years. I don't recall where I picked it up but probably from a swap or garage sale. Somewhere I believe I have paperwork on it.

I just dug it out of the garage and put the antenna analyzer on it. Surprisingly it dipped at 25.88 MHz. This is without any tuning of the cap or any cleaning, etc. So, it's probably for mobile CB direction finding and with a little cleaning and peaking.

Ref - PVC Pipe:

The WHITE PVC pipe is used for plumbing and is NOT UV protected = with time it will crack due to the sun's UV rays. The GREY PVC pipe (used for electrical conduit) has UV protection and can thus be exposed to the sun. Printed on it's side it says, "for Indoor and Outdoor use, Sunlight Resistant" I just bought some 3/4" diameter, GREY conduit to make an Alford Loop Antenna (I believe it is also known as Cross Parallel Loops). Plan to use 3/8" "soft" aluminum tubing for the loop and the grey PVC pipe as the support structure. Prefer Copper Tubing, but it is expensive and heavy.

I'm told that the same characteristic that gives it its UV protection, also adds a small loss factor to the conduit, making it absorb and dissipate some of your RF signal. I think it is supposed to contain carbon.

I want to believe that the effect is (hopefully / usually) marginal and something we don't need to think about.

On the other hand, I have read an account from someone who used PVC to make their antennas, where suddenly the antennas stopped working right. It was eventually traced to a vendor change in the supply of PVC from the hardware store. So it can happen.

The test of putting a piece in a microwave oven to see if it gets warm, is great if you are making 2+ GHz antennas, but I doubt it has much relevance on LF/MF/HF.

Looking for "economical" sources/leads to buy non-inductive 2-10W terminating resistors for T2FD/Rhombic type antennas.

Any designs on making a loop "terminating resistor assembly" to accommodate 125W HF input?

I have some white PVC that has been out in the sun for
years and is doing fine. OTOH, I have some gray PVC
that turned brown on the surfaces exposed to the sun
after only 1 year.

The microwave oven test at 2 GHz may seem irrelevant
to low frequencies, however, it turns out that the
loss tangent of all plastics I have ever looked at
is fairly constant with frequency. Basically, only
polyethylene, polystyrene, and teflon have low loss
(at all frequencies). Other plastics are like PVC.
PVC is a lossy dielectric at all frequencies, no
matter who makes it.. I suppose it could get even
lossier if it was loaded up with carbon or lead, etc.

Hi ALl,

I have a complete RACAL kit which I could be pursuaded to part with

This has terminal resistors that nicely fit onto the stakes that are
used to tie down the two sloping wires (Kevlar)

Need 12m mast as its centre and the handbook says it is best for freq
up to 30 from about 8 MHz

I recall many years ago in QST someone had the traps on their antenna develop carbon tracks from arcing. He knew something was wrong when the SWR suddenly went up.

I suspect if he'd wound them longer, they might have withstood more power.

However, he didn't report problems before the arcing occurred. And that was with a parallel tuned circuit (ie, high voltages) wound directly on a piece of PVC. For a transmitting loop, the high voltages will be present at the ends of the loop and so the capacitor is the limiting factor.

As to sun protection, there is always paint.

White PVC doesn't show sun damage because it remains white but becomes brittle. Grey PVC seems to show it by shifting color. However, I think the color tends to block UV from penetrating more deeply.

Not ALL paint is equal for UV protection on PVC pipe. I can tell you in the fabric covering of airplane surfaces (ailerons, elevators, etc.) to protect them from the suns UV rays a "special" primer and paint are used to make the fabric last long - not just any paint. Sorry to complicate things, but this might be helpful info. A company that sells paint for this purpose is Poly Fiber in Riverside, CA. There telephone number is - (800) 362-3490 [NO I do not get a commission.]

There might be a wrapping tape that does the same thing.

I would guess they are acceptable for receiving loop antennas, but you wouldn't want to use them in a transmitting antenna where the circulating RF currents get pretty big!

But that's only a guess.

Bingo!

Adding carbon makes it much more lossy. Carbon is a conductor. Not a
very good one, too.

It might also change its loss vs. frequency characteristics.

I'm not saying it makes enough of a change so that the microwave test
is irrelevant, but it might.

Of course if you're using the PVC only as a support structure, then it hardly matters, and I'd go for UV resistance even if it is RF-lossy.

But for trap coils, or an antenna enclosure on 146 or 440, I'd be "more" concerned. Not enough to reject it outright, but enough to want to investigate.

Andy,
I quite agree, a puff of RF would no doubt destroy a polyvaricon hi!
Many of the commercial designs with tuning facility just don't seem to have the space for more than a variable capacitor of this type.

7887. DF loop to locate local 20m broadband interference

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-09-30 22:26:47 UTC
From: Eamon Egan
Topic: 7887 Message: 7887

I often experience pretty bad local broadband interference on the 20m band and I want to be able to track down the source. It seems powerline related as it sounds like it's modulated at 60 or 120Hz. It may be on other bands as well, but I am mostly active on 20m at this point. When it happens, it is often reaches up to between S5 and S7 or sometimes S9 on my 20m dipole.

It could conceivably be from somewhere inside my house but I am pretty sure it is from somewhere nearby outside. I plan to move up and down the street with my transceiver on battery power and connected to a loop antenna, to see if I can null out the interference source and thereby locate it. Before I move around on battery power, I will be 100% sure it isn't in my house by momentarily cutting off the AC.

I would like to have some ideas or advice on what sort of loop antenna would be best for this purpose. I already built a pretty crude square shaped loop on two wooden crosspieces, roughly 4 feet across. I was not overly impressed by its directionality, but then again, I did not play with it very long. I only tried rotating it inside my house near where the transceiver is set up. Maybe this will be fine for my purposes.

I don' t need a super sharp null, but I do need to be able to see it well enough to walk in the right direction and stop in front of the right neighbor's house or utility pole :) I know that a simple loop will give two nulls at 180 degrees from each other, and I can deal with this ambiguity.

So here are a few more specific questions:

* How many turns, at what diameter, would be best? Is one turn better or worse than several? Are there any relevant design formulas that yield this kind of guidance?
* What construction details or tolerances are most critical, for the loop to display a useful null for this type of direction finding?
* Do you think I should bother trying to make it shielded (i.e. use coax cable for electrostatic shielding)?
* Should I tune the loop with a variable capacitor? Will this help me in what I am trying to accomplish?
* How important is balance in achieving a useful null? Should I connect the loop to my transceiver with (unbalanced) coax, or use the 300 ohm balanced line terminal on my tuner? Or should I make a separate balun using a ferrite toroid?

Any ideas or advice would be appreciated. I mostly want to know whether I should just start with something very simple like what I've already built, or whether I need to put something fancier together for this application.

Eamon Egan, VE2EGN

Topic: 7887 Message: 7888

I am certainly no expert, but I'll throw in my beliefs and opinions.

With loops, there are small loops (much less than a wavelength), and large loops (similar to a wavelength). The two behave totally differently. The small loop has nulls perpendicular to the loop, whereas a full wavelength loop's null is exactly the opposite. Between the two, you probably get a mishmash of both patterns, with no good null. So keep the dimensions small.

I *think* the dimension in question is the total wire in the loop, so it would seem that a single turn loop might have better nulls than a multi turn loop with the same outer dimensions. For a loop to be considered small, the current in the wire should be everywhere the same. Once the wire length starts to approach a quarter wavelength, that no longer holds true.

Bigger size means more signal gathering capability (more gain). If you get enough signal with a smaller loop, there may be no reason to make it bigger.

Electrical balance is supposed to be an important characteristic for having good nulls. If you unbalance the loop it might screw up the pattern.

So-called "shielded" loops supposedly help maintain that balance.

Tuning the loop with a capacitor increases the amount of signal it receives (its gain), but I think wouldn't affect its pattern. If you get enough signal without tuning it, maybe it's good enough.

Regards,
Andy

Build a loop like this:

http://www.mtmscientific.com/swloop.html

using a 365 pf tuning cap and some wire (I used insulated stranded 12 ga hookup wire).

Use Bruce Carter's Calculator:

http://www.angelfire.com/mb/amandx/loop.html

1 turn of wire on a 44" x 44" frame, and 365 pf tuning capacitor should do well.

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-10-01 17:09:23 UTC
From: vbifyz
Topic: 7887 Message: 7890

I tried this at my QTH (typical suburban subdivision) with both tuned and untuned loops. At 14MHz, a 1m diameter loop is already quite big and the null is not deep at all, but it is still there. Tuned loop gives a better null. I used 10-360pF air variable capacitor for tuning and a 15cm diameter coupling loop. The untuned loop was a 1.5m piece of wire connected to the 50 Ohm input and the ground lug of my FT-817.

In my case, I wasn't able to isolate the source. The QRM is radiated from all wiring everywhere in the neighborhood. The only way to reduce it is go at least 50m from all houses. When you move around the powerlines, the direction changes randomly, there is no "point source". It also changes with frequency, i.e. the 14MHz null and 7MHz null may be 90 degrees apart.

I may have found a maximum around 3 or 4 particular houses, but that was the extent of my "direction finding".

Good luck, 73
Mike

Topic: 7887 Message: 7892

Thanks to all who replied so far.

Andy: I was aware of the distinction between "large" and "small" but thanks for mentioning that it is the total length. that seems to make sense. I will keep the diameter small enough, stick with a single turn, and possibly simulate the antenna to see at what size the pattern starts getting complicated.

Paul: thanks for the recommendation on the site for the kit, and the calculator. These look helpful.

Mike: thanks for mentioning how difficult it can be to pinpoint. I will not place my expectations too high. And of course even if I do think I know where it's coming from, knocking on the front door and explaining that they need to stop interfering will not necessarily be easy. You seem to be saying that your untuned loop connected to your receiver (1.5m) was longer than your tuned loop (you call it a 15cm diameter coupling loop). Isn't the loop connected to the radio usually called the coupling loop, and isn't it usually smaller than the tuned loop?

I have two different opinions on whether the tuning capacitor affects the pattern or just the signal strength. I may simulate this to form my own opinion, or since I have a serviceable tuning capacitor I may just have a go at tuning the loop anyway, just to see how it goes.

One more thing I'd like to ask for comments on: does anyone know why it is better to use a separate coupling loop, as opposed to connecting the tuned loop directly to the radio? I know coupling loops are used in transmitting loops also, but I am not sure I understand why. What would happen if you tried to connect the tuned loop directly to the radio?

I have found an answer to my own question about coupling loops, at
http://www.radiobanter.com/showthread.php?t=74935

Apparently the impedance ratio equals the square of the diameter ratio. So
it is a matter of impedance matching.

Hi,
I have been reading various reports etc on the AOR LA-390 loop antenna
and in each case it says the loop is 300mm dia x 60mm dia.
From the photographs it certainly does not look like a 60mm dia tubing element ????
Can anyone using one or having seen one pass comment please ?????

The 60 mm. size refers to the thickness of the loop, it is determined by the
dimension of the band switch box at the bottom of the loop.

Easiest way to track down RFI is to walk your neighborhood with a battery operated portable broadcast band AM radio. It has a ferrite loop built into it.

7897. Very interested in a loop antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-10-04 22:45:23 UTC
From: klelfmm
Topic: 7897 Message: 7897

I'm looking to add a loop antenna to my radio set up. I live in a large city in Southern California and at certain times of the evening my radios seem to be plagued with noise, even outside. Right now I have been using a "trap" wire antenna which works well but the noise can be unbearable at times. AM can be so noisy that I can only receive a few stations and this shows up in some of the shortwave frequencies as well. I've walked around the neighborhood and it seems to be a large scale noise problem. All wires are underground so I don't really know what is causing it. At 4-5 AM (sometimes much earlier) everything is perfectly quiet and the stations I can hear are incredible. Daytime is pretty good too.
I like the idea of using a loop with a rotator to null out some of the noise.I've looked at the nice Wellbrook antennas. I'd really like to build one if possible and was wondering if there are any home built loop antennas that can compete with a Wellbrook? Any that are not too complex to fabricate? Any help would be greatly appreciated!

It sounds like you have a noisy RF emitter somewhere near your neighborhood.Try a walk around your neighborhood with a portable SW radio if possible and see if you can localize it. The higher in frequency you can hear it, the closer it is. What businesses nearby are closed during the 'quiet time'?

There's plenty of information available that will help you make a loop antenna that will work every bit as good as the Wellbrook and cost far less. The details for the loop proper can be found in the "Shielded Loop Aerials Rev 0.pdf" file in the group files section, and the amplifier can be found in the "Wideband Loop Antenna Amplifier RevA.pdf" file that is also in the group files section. Simply ignore the remote tuning portion of the first paper and replace it with the amplifier of the second paper.

There is a shopping center that is fairly close by. There is one or two houses were the sound seems to really peak at. When I walk at night with my portable with headphones the strong local Los Angeles station on 640 AM completely dissapears and there is no reception of anything on the AM band. I'll take my portable SW out and give it a try on higher frequencies. Thank you!

At the following sites you will find a number of active untuned small magnetic loop designs. They have been subject of dicussion of this Group recently, so when you go back in the archive you may find a number of remarks on them.
Chris Trask already pointed you to his designs in the groups file area

http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna.htm

http://xephemera.blogspot.com/2009/08/16-30-mhz-broadband-low-noise-loop.htm
l

http://www.qrss.thersgb.net/active-loop-receiving-antenna.html

http://wl1030.com/content/

In your circumstances a passive tuned or untuned loop may be a good start of experimentation when you can't get rid of the RF interference. Certainly a shielded coax loop is very easy to build and could give you quite an improvement.

Alex,

14 years ago I performed noise (E Field) imunity tests with two prototype Wellbrook ALA1530. One was screened and the other not. The tests were performed below about 4MHz. As far as I could determine there was no imunity improvement with the screened version verses the unscreened Balanced loop. The reason for not conducting the tests above 4MHz, was because at HF the near field (H) distance from the loop where the E field rejection is high, is too close to the antenna to make any meaningfull comparisions.

Kind regards

Andrew Ikin

Andrew,

Thanks for responding with the results of your testing. I wanted to know if anyone had done these comparisons and your experience is similar to mine. A dozen years ago did this kind of test comparing various, unamplified, 'untuned', same dimension, coaxial type shielded loops using RG-58, RG-59, RG-6, RG-6Q, versus a variety of unshielded loops and found no significant difference in presumed local E-field transients and electrical 'noise' measurements. What I did find is a lowering of the natural resonance of the loop when shielded, and changes in the resonant 'Q'. After having spent a large amount of time looking at IEEE and IRE papers over the years, haven't found any comparison paper quantifying the differences, and/or immunities to local noise, if any. What I have found, is a lot of marketing claims, loads of opinions and impressions, many published in the amateur literature, but no hard comparative numeric data on the subject. Much of the data that was found did not address the resonant frequency shift and 'Q' differences which should have been compensated for in these articles.

Maybe someone else in our group can share their experiences on the subject. If anyone has some test data to share that would be great.

Best regards
Alex

Are you able to null out the noise significantly with a portable AM radio and its built-in loopstick antenna? If not, the noise may be so strong that even a larger loop will not solve the problem...as well, if there is more than one noise source, the task will be even more difficult. The real problem is the noise and that is what should be tackled as a first line of defence...first try to gather as much data about the noise that you can collect...is it time dependent?...any particular direction from your home (here is where the portable radio comes in handy)....what are it's characteristics? Nowadays, most of this stuff is coming from switching power supplies which seem to be part of every modern day appliance. The switching pulses can radiate along the powerlines and even a source a block away can seem like it is coming from next door. Low voltage halogen lamps (like a string of pot lights) can create a terrible racket as can light dimmers and plasma TVs. Try and tackle the source first. Eliminating the source is the best solution.

7910. Pixel Technologies RF PRO-1A Shielded Loop vs Wellbook ALA1530

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-10-09 16:31:10 UTC
From: lexluthor6969
Topic: 7910 Message: 7910

I have been using the new Pixel Technologies RF PRO-1A loop .

http://www.pixelsatradio.com/PDF/RF_PRO-1A_Cut_sheet.pdf
<http://www.pixelsatradio.com/PDF/RF_PRO-1A_Cut_sheet.pdf>

And also running side by side tests comparing it to the latest version
of the Wellbrook ALA1530

http://www.wellbrook.uk.com/antennashop/index.php?route=product/product&\
path=20&product_id=34
<http://www.wellbrook.uk.com/antennashop/index.php?route=product/product\
&path=20&product_id=34>

Both antennas are somewhat similar in size and price.

- The Pixel antenna is made in the US, while the Wellbrook is made in
England.

- I believe both antennas have 30 db (approximately) low- noise preamps
that cover up to 30 MHz

- Both are broadband "receive-only" antennas that require no tuning
adjustments

- I believe both have noise-figures in the 2 -3 dB range

- The Pixel antenna has substantially better IMD specs (OIP2 > 100dB,
OIP3=48dB) vs the Wellbrook (OIP2 = 80dBm, OIP3 = 43 dBm). This is
significant in locations where there are strong AM broadcast band
signals and other high power signals present that might overload the
amplifier.

- Both amps have internal low - pass filters that knock out local high
power TV and FM stations above 30 MHz that could overload the amp

- The Pixel loop is a shielded 2-turn (effective) Moebius configuration
(similar to the antenna Chris Trask has described elsewhere) while the
Wellbrook is a traditional unshielded single-turn configuration. The
Pixel and Trask antennas are based on the work of Dr. Carl Baum who
developed this architecture for a classified US Air Force project.

- Both are about 1 meter in diameter

- Both use 3/4 inch aluminum tubing construction.

- The Pixel antenna is anodized a satin gray color to prevent
corrosion. The Wellbrook is natural aluminum not anodized

- The Pixel antenna weights a little more since it has a center support brace that provides more support for the Moebius junction box .

- The Pixel antenna is provided with a standard L-bracket, U- bolts and saddle clamps to mount it to a flat surface or any pole up to 2 inches in diameter, while the Wellbrook does not include these items and it's up to the user to improvise mounting

- Both can be used at ground level to provide good reception. In my setup I have them mounted about 6 feet off the ground on rotors.

- No special grounding for good signal reception is required for either antenna, although the Pixel antenna has a large lug to attach a grounding wire to provide standard lightening protection.

- Both antennas include a power supply and power inserter that duplexes power and signal onto one cable lead that goes to the antenna and preamp

- The Wellbrook uses standard BNC connectors on the antenna which must be weather- proofed while the Pixel uses water ☐proof F-connectors that are provided

- The Pixel is designed to work with standard low- cost RG-6 75 ohm cable (the same as that used with satellite TV dishes). There is an impedance matching device and PL-259 adapter to mate with standard 50 ohm input Z radios. Wellbrook recommends RG-58 50 ohm cable that must be fitted with BNC plugs.

- The low- noise amplifier in the Wellbrook is encapsulated in tamper ☐proof epoxy in an unshielded plastic enclosure that is attached to the aluminum loop structure. There is no easy way to remove it from the loop or get access to the interface between the loop and the amp to insert, for example, a broadcast AM radio band elimination filter in certain circumstances. This configuration makes the amp very difficult to repair or replace. I'm not sure how Wellbrook deals with this, but sending the entire 1 meter antenna to England for repair has got to be an expensive time-consuming process. On the other hand, the Pixel amplifier is a separate assembly that is mounted inside a metal shielded enclosure that attaches to the loop antenna through a short cable that is easy to access to add input filters or remove for repair or replacement.

- Pixel at present only sells this in a North American version while the Wellbrook is available with power supplies for Japan, Europe and North America. Both companies provide highly filtered specially designed low- noise linear power supplies. The Pixel has an internal self-reseting fuse to protect the supply in case of an inadvertent short or over current condition while the Wellbrook has a standard user-replaceable slow-blow fuse for protection. The Pixel has a high voltage discharge- tube for lightening protection on the lead in wire from the amplifier. I'm not sure if the Wellbrook provides any special protection for induced high-voltage transients on its lead in wire.

- The Pixel antenna includes an internal Transmit /Receive switch that permit the user to optionally connect it to a transceiver's "KEY" output to automatically remove preamp power and also disconnect it from the receiver when you are transmitting. A handy feature if you are mounting the loop in the vicinity of a transmitting antenna. With the Wellbrook, you need to purchase a T/R switch separately or place the antenna at least 80 feet away from the transmit antenna. The Wellbrook's amplifier when it is saturated outputs nearly 1 watt into your receiver which could cause damage in some receivers, so some considerable care should be taken when using this antenna in conjunction with a transmitter. Since the amplifier has nearly 30 dB gain, it does not take much power coupled from a transmit antenna to saturate it.

- I'm using these antennas with a software □defined- radio (SDR) that allows me to view and receive the entire 30 MHz spectrum at one time. These kind of broadband loops are a perfect match for SDR's since no narrow- band Hi-Q antenna tuning is utilized.

- From the standpoint of performance, definitive side- by- side tests of the two antennas is still a work in progress but my initial reactions are that the Pixel antenna has the edge especially at frequencies below 10 MHz where the Moebius loop provides a very noticeable improvement in received S/N. More definitive quantitative results will be provided in a future post.

- Both antennas exhibited very impressive and significant rejection of local near-field QRM and mains/power line radiated noise as compared to common E-field electric antennas. I'd say they were both equal in this regard. Both had the classic "figure eight" reception pattern with very sharp 30 dB nulls at right angles to the plane of the loop.

- Andy Ikin from Wellbrook has posted results of side by side tests taken at a test facility of a Moebius antenna he made compared to his improved ALA1530. He used a magnetic signal source in near-field conditions. From these tests he concludes that the Moebius is vastly inferior above 18 MHz. However I have not been able to observe these results with reception of real-world far □ field signals. The tests he did only considered near- field reception of H-field magnetic signals. Both kinds of loops have significant E-field response as well as H-field response to far field-signals. It's possible that the increased loop area (a factor of 6 dB) of the Moebius loop provides superior E-field response that compensates for the lower H-field magnetic response he observed. The jury is still out on exactly how the physics of all this works since the Moebius loop is new to the shortwave community. But so far this evaluation, Chris Trask's results and the observation of others that have built these new Moebius loops seem to confirm the superiority of the Moebius shielded loop architecture. More later.

Thank you Steve. No I can't null it out with a protable AM radio. The noise comes on between 3 and 4 PM and usually, but not always lasts all night. At first I was thinking mabey the street lamps. But several times I have heard nothing as far as noise waking up and tuning in at 2 or 3 AM and the lights were still on. I'm not sure what it is. Last night I could only get the local clear channel KFI and a couple other strong signals on my portable Zenith Transoceanic radio as I walked the neighborhood. During the day there is never noise and the noise level is very low.

If you are unable to null it with a portable AM radio and it's built-in loopstick (these things are very responsive and highly directional) then it is unlikely that a loop of larger aperture will null it effectively either. Your 'evening' noise source is something that may or may not be coming on automatically. Carefully noting the switch-on times will indicate if it is on 'auto-mode' or if it is being manually switched on. If you are living in a strictly residential neighborhood then some of the obvious sources will be backyard or security lighting, or porch lights. It sounds as if they may be manually shut down (at bedtime??...again...watch the timing) but sometimes they are not which may hint that they are not inside a house but, being outside, are sometimes forgotten to be switched off perhaps. The fact that it cannot be nulled may also mean that it is extremely close and that you are basically sitting 'on top' of the source. Have you eliminated your own house completely, as the source??

Your best solution to this noise problem will not be via different antenna systems but rather by finding and eliminating the source if you can. Time to put on your Sherlock Holmes coat!

I have similar situation here in the Westminster-HB area. What general area of LA-OC county are you located where this late afternoon interference is happening? If it's in the beach cities, the marine layer comes in about 3-4 PM and salty moisture immerses and/or lays on the high tension line insulators which then arc/spark creating broadband noise and wreaks havoc on reception.

you need to look closely at the M=2 Baum Moebius device as the M=1 is not really effective at noise reduction IMHO

you need to read the original Dr Carl Baum notes on the higher order Moebius antenna devices he developed and used

best Paul VE3PVB

I'm interested in knowing if anyone has done testing between the mobius and any other loops comparing numeric S/N or NF or 'transient' E-field "noise reduction". Would like to see the test data.

Howdy All, Name is Ken. Mostly I'm interested in large loop antennas. I curently have a full wave vertical loop for 40 meters (142 ft. total,top at 60 feet or so,bottom at 30 ft.). I also have many other hf antennas up- I live on top of a hill in the Ozarks. I'm looking to get more active on 80 and 160 meters, thus my interest in large loops. Thanks, Ken AC0ML

If a loop null is inconclusive, you may be able to use a radio location method sometimes used for search and rescue. Using signal strength alone, you pass in a straight line, continuing past the maximum signal, if possible from zero signal to zero signal. You then turn 180 degrees and go half the distance back again. You then turn either left or right and you either get to the signal source, or move away from it. If the latter, just do another about turn and you will get there. I appreciate that street layout etc may not lend itself to this, but you may be able to apply the technique in some form or another.
VHF is notorious for reflections. It may pay to use a portable beam on a handheld or mobile from 3+ locations some distance away, and attempt a triangulation fix.
Sorry a bit off loop topic.

From: Andy
Topic: 7919 Message: 7921

Welcome, Ken.

This seems to be a good group for all loops, large or small.

There are a couple of other Yahoogroups about large loop antennas, including [Skywires] and [LoopSkywire]. If I remember right, one or both groups may not be moderated very well so expect some spam on them from time to time. (Or maybe I'm thinking about two different groups...)

Andy

> The noise comes on between 3 and 4 PM

About the time kids get home from school and turn on their TVs, right?

> and usually, but not always lasts all night.

But earlier you said it's often gone by 4 AM, which might be when the
last of the late-night-TV-movie-fans has given up and gone to bed.

If there's more than one TV (or whatever) causing it, it could make it
impossible to null out because you can't null all of them at once.

Just some thoughts.

Andy

Hi Paul,
Thanks for your info. I think I'm missing something. I've read Baum's paper several times, but don't see a reference to the M=2 viz M=1 reference in his paper. Can you point me to what I'm not seeing? The Baum paper I reviewed is "Characteristics of the Moebius Strip Loop" Regards,
Alex

Resistive termination! Solved my noise problems!

We discussed this a while back when somebody posted a question about T2FD antennas. Most seemed to decide that losing no less than half your signal through the resistor wasn't worth it. Taking that position completely ignores the advantage of using resistive termination antennas.

If your noise problem is off frequency (most all of it is) then the real problem is front end overload. You first have to reduce the strength of undesired signal to the point that your receiver can reject it, then try to tune in your desired signal.

Historically, the popularity of using resistively terminated antennas went out with spark gap transmitters. Talk about splatter! Back then those operators knew how to best work around off frequency interference. Resistive termination used to be a necessity. With all the electromagnetic noise nowadays resistive termination is again a necessity for people plagued by noise problems that can't be solved any other way.

Tracing down a noise problem might help, but you may not be able to do anything about it even if you find it. In my case; The power company refused to do anything about their insulators/splices (you could even hear it without a radio), and the neighbors weren't going to do anything about their noise either. That really didn't matter because I caused some of my own noise problems, but I needed to keep those computers running. Directional antennas often don't work well for noise problems because every conductive object will absorb and re-radiate the noise.

I'm glad I re-discovered the advantages of using antennas with resistive termination, because nothing else worked. There are limits to what you can do with resistive termination, but if your desired signal isn't extremely weak (DX) start experimenting.

> Resistive termination! Solved my noise problems!

I don't get it.

Are you saying that by adding a resistor at a special location in your antenna, you changed its directional pattern so that it no longer receives the low-angle noise sources while not reducing the desired signals?

Or that by using a dummy load instead of an antenna, all the noise is gone? (Hint: There's an easier way: it's called the power on/off switch.)

If what you're saying is what I think you are saying, you recommend using an inefficient antenna, as a means of making it more 'deaf'. I hope this is only your receive antenna you are doing this to, not your transmit antenna. That would be a waste if it were, to be doing it on purpose. Especially since there are easier ways of reducing the received signal while not affecting the transmit signal (such as the ATTenuator switch or the RF gain control, both of which affect only the receive side).

Regards,
Andy

7928. Ferrite bar loop antenna experiments with the Satellit 750

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-10-12 14:09:16 UTC
From: salmonguyrep
Topic: 7928 Message: 7928

An interesting experiment last night using my Satellit 750 and two different home brew ferrite bar antennas; one made from a 19" 125 mu and one made from a 27" 125 mu ferrite bar□both purchased from Stormwise and both with a primary coil made from 38 turns of 630/46 Litz wire, where the 27" antenna also has a secondary pick up coil of 4 turns placed over the center of the primary coil. It was a perfect fall evening in Houston weather-wise, and so I moved my equipment to a small roof deck about 50' above street level, at a location that is RF quiet compared to my usual indoor location.

The 19" antenna inductively couples to the ferrite bar antenna of the Satellit 750. Previous tests demonstrated essentially no difference in the magnitude of RF gain when comparing the 19" and 27" antennas using inductive coupling, as confirmed in the more RF quiet roof deck location. The Satellit 750 is a fun radio to use because you can manipulate both the RF gain and the volume for optimal reception. The 19" antenna, inductively coupled, overloaded the radio when the RF gain pot was set at 3 o'clock or more. The 27" antenna when direct coupled to the female jack on the ferrite bar antenna of the Satellit 750 (another really nice feature for antenna experimenters) was much quieter than the 19" inductively coupled antenna, so much so that I had to run the RF gain control at maximum level to be able to hear much of anything. When I interposed an old BAX-1 RF broadband preamplifier between the 27"er and the Satellit 750 ferrite bar antenna the radio overloaded even with the RF gain control set at the most minimal level.

The nulls were sharpest with the 19" antenna, although the 27"er is mounted on a tripod so I could get some additional nulling with it by using the altazimuth adjustments possible with the tripod and not possible with the 19"er inductively coupled to the radio.
All in all, the 19" antenna provides the best combination of RF gain, nullability, and portability. Tonight I will test this set up versus the 27"er direct coupled to an E1.

73s;

Salmonguy

No, not the pattern.
> If what you're saying is what I think you are saying, you recommend

Yes, but mostly more "deaf" off frequency than on frequency.
> I
> hope this is only your receive antenna you are doing this to, not your

For some antennas you would want to switch out the resistor, for others
you can leave it in (e.g. T2FD, terminated resonant rhombic)
> there are easier ways of reducing the
> received signal while not affecting the transmit signal (such as the
> ATTenuator switch or the RF gain control, both of which affect only

But that attenuates everything equally, not off frequency signals more
than on frequency signals the way a resistively terminated antenna can.

Guys, Guys, leave the resistor out.

All resonant antennas are bandpass filters, resistor loading broadens them just the opposite of what you want.

Seriously!

7931. Spiral MW loop design (Short Wave Magazine around 1990)

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-10-13 23:43:53 UTC
From: nickbeee
Topic: 7931 Message: 7931

Hi,

Just joined this group. Does anyone recall a design for a spiral medium wave loop that was published in Short Wave Magazine around 1990? The loop was wound in a heaxagonal shape and the article included details of how to make your own litz wire by taking a few strands of 36 gauge wire and twisting them together with a drill.

Well this was an unfinished project that I was hoping to complete. I've got most of the parts including my reel of DIY litz wire but I've lost the original article. Can anyone help me with a description of the design or a copy of the original article?

Many thanks,
Nick.

I've almost completed my loop... Just need to finish off the feed from the coupling winding and make a base for it. I ended up with 10 turns of home-brew litz and a 500pF variable capacitor. Tuning is very sharp so I have a reduction drive with a vernier scale to fit.

Initial tests with it sitting next to my ICF2001D sound promising.

If anyone is interested to see what it looks like I've uploaded some photos to

Hello Brian,
There is no need of an excuse of any kind. I knew so well, because I myself made the same "mistake" many times over and I am only 62! And, I just went to the indicated adress and downloaded the page. It happened to be a design for which I have the components laying around waiting to be built into a nice active loop. I have found this design from different sources now, all with different transistors in it, so it appears to me to be a kind of generic design. They have one thing in common, all those that built it have a very positive judgement on it.

Regards,

Cor Beijersbergen

This may be a basic question but I'm new to loop ants...

What would be the significant differences (performance, etc) to a spiral loop constructed in a single plane to a loop of same turns count but with 3D parallel turns (hope this makes sense)?? I am asking wrt primarily MW reception only. Tnx for any/all replies.
Briggs in Gloucester, Ma.

From what I've seen they were popular in the early days of radio. They accomodated the need for a loop antenna mounted to the back of a radio...

Consider they early radios were large and some floor models. IN any event it would have been cumbersome to have a large broadcast band, 550-1600 KHz, loop in the house!

The basket weave was developed out of need. and it worked great. Some pieces of art!

Google dr ace super loop and you will get a whole bunch of sites with details of super loop antennas. Radio Works sells a a couple of models of super loop antennas and has details on their website. dxzone.com has a bunch of info on super loops as well.

I am thinking of putting one up after the leaves fall off the trees.

Has anyone in the group tried one or modeled one?

Brian,
That would be one of my creations, or should I say modifications. It was my own loop "head" coupled to a Ramsey Signal Magnet. It worked well and did an excellent job shielding noise out, (as did the stock rod assembly). Refer to msssages 655 and 686 in this group and various posts from #6-27 in the "ferriterodantennaexperimenters group.
Let me know if you need any more details.

Here's a link to the kit, which i think is still available.
http://www.ramseyelectronics.com/cgi-bin/commerce.exe?preadd=action&key=SM100.

Dr. Ace's site is apparently gone now. What a shame, an excellent resource!

This antenna is called the Super Loop 80, and here are two similar ones to the one on Dr. Ace's site:

http://larc.hamgate.net/SuperLoop.htm

http://www.radioworks.com/csuperlo.html

http://www.iw5edi.com/ham-radio/30/super-loop-antenna (same as the first link)

I have the picture from Dr. Ace's site. It shows the wires on top to be each 49'9", or, roughly 100' across the top.

The diagonal wires are each 59' sloping down to the balun, which is 4:1 current balun. The ladderline stub, which is wired across the top center insulator, is 29' 10" and shorted on the bottom.

From the 4:1 balun, 50 ohm coax back to the shack.

For the Super Loop 112' across the top, of course, each horizontal wire would be 56', less a little bit for the insulator, and the diagonals would each be 63.5'. And that shows the stub to be 30'.

I know of a number of hams using the Super Loop 80 to good effect.

Van,
I got time to try the link given and found it opened first click,
so it appears all is well.

Hi riggs in Gloucester and the group,

I am a little unsure if I have understood your question correctly but here goes anyway :-)

When you wrote "spiral loop constructed in a single plane to a loop of same turns count but with 3D parallel turns" I took this to mean side-by-side windings as compared to "basket weave" windings.

If so then the most significant difference between the regular side-by-side winding and the 3d basket weave is that basket weaving reduces the self-capacitance of the windings which roughly translates to the possibility of a lower loss winding (higher performance/Q), sharper tuning and maximised tuning range.

Self capacitance is an unwanted side-effect of winding a coil so if the self capacitance can be minimised then the performance of the coil/loop will be better plus basket weave looks cool too :-) Basket weave would allways be my first choice for a MW tuned loop antenna.

Hope this helps?

7966. Hexagonal Loop Antenna - Needs improvement.

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-10-19 21:42:45 UTC
From: Nick B.
Topic: 7966 Message: 7966

I played around with this antenna using the 1-turn coupling loop fed into my RX320 Receiver. Results seemed average, I can null strong locals but the tuning seemed to get flatter the higher I go in frequency.

I've run a few approximations through RJELOOP3 and realized that the output impedance of the 1-turn loop to the receiver is going to be anything between 500Ω (500kHz) and 2k4Ω (1700kHz). Sticking this straight into the 50Ω input of a receiver is seriously degrading the Q of the loop, getting worse as the frequency increases. I think the design as it stands needs an improvement, the simplest one I can think of being a broadband matching transformer with a 16:1 ratio. Can anyone recommend a design?

I'll put some ferrites on my shopping list when I visit QRP rally at the weekend. I could also try a spare Wellbrook UMB130 although that's only 9:1.

BTW I've slimmed down the PDF in the files section from 3M to 800K.

Try a balanced hi impedance (FET) amp.

The ability to use a balanced amp is the advantage a box loop
(basketweave or not) has
over a spiral wound loop. The box loop would be centertapped to the
amp gnd and the two
ends tuned with a dual gang variable cap, and the two amp inputs
connected at these points.

John

Thanks but I'm trying to avoid an amplifier in this case. Some free
time to hunt around for articles on transformers tonight and this one by
John Bryant came up :
http://home.comcast.net/~markwa1ion/exaol2/z_transformers.pdf

So hopefully I can get my hands on some -75 and -43 toroids this weekend.

From: kugellagers
Topic: 7970 Message: 7970

Is there anyone who has a copy, can make a copy or scan an old article from The Lowdown?

Specifically I am looking for this article:

"Analysis & Design of Broadband Low Frequency Loops," Lowdown, April and May 1985

Thanks,

John

Are you sure about those dates? There's an article "Broadband LW Receiving Loop" in the May 19895 issue, and nothing in the April 1985 issue.

I got the reference for the article from here:

http://users.tpg.com.au/users/ldbutler/VLF-LFLoopAerial.htm

So I am not sure other than that.

The article in the link as I am re-reading it says "... is described in the April 1989 issue of Lowdown (ref 3)."

But the reference labeled as 3 in "References" section at the bottom is exactly as in my original request.

Maybe it is actually from the 1989 issues?

If nothing else can be found matching the reference in the link I would also be interested in reading the article with the title you mentioned.

Cheers,

John

7977. Quantum QX Loop for sale

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-10-24 16:11:59 UTC
From: neilbellgroups
Topic: 7977 Message: 7977

I have a Quantum QX Loop v2.0 PLUS for sale. I have two loops and find now that I only need one since I am rearranging my listening posts. The Quantum loop is a great DX tool. It sells or $239 plus S&H. see this for more info:

http://dxtools.com/QXv2+.htm

I would like to sell it here before I have to put it up on eBay. Asking price is $165 which includes shipping by priority mail! It is relatively new, acquired this year. Includes the AC Adapter and a 3 foot coax cable.

My eBay rating is 100% positive, user name is "neilbell"

Contact me in the next 5-6 days by E-MAIL, not on the group. I accept USPS money orders, paypal or personal check (10 days to clear).

Thanks for reading this,

Neil Bell

The wire or insulation should not ne a problem. When you say disappointing results are you comparing it to a different antenna? I do not have experience with the ALA 100 but my understanding is that it should be very quiet, so make sure you are judging it on signal to noise ratio instead of the straight output level.

Hi Jason,

I installed an ALA-100 a few months ago and it is now my main E/W antenna for Dxing NDB's. Performance is equal to the PA0RDT as far as signal strength. This is usually a very quiet antenna except for occasional man made junk/rubbish RF.

My loop is a rectangle 32ft long x 12ft high (88ft circumference) in a fixed position with the bottom wire 3ft above the ground and the antenna module mounted on a short pole in the center of the bottom wires. I used these dimensions which are slightly greater than what Wellbrook recommends as I had two supports that were already in place 32ft apart. The wire I use is normal insulation 20ga stranded. Normally in my experience the type/size of wire doesn't matter much for receive antennas except for the obvious mechanical strength and mixing of different materials that could cause corrosion. I have also insured that 12vdc is at the ALA-100 Antenna module through a 100ft run of coax. I have also installed a 7ft RF ground stake in the ground near the antennas and common mode chokes on all coax ends.

Would be interested in what you mean by disappointing results??? If you can't resolve the problem you may want to contact Andy Akin at Wellbrook. I wish I had installed this antenna sooner! Hope to reach 1000 logs by the New Year!

Hello Chris,

If one looks on the internet for opinions on shielded vs un-shielded loop antennas, they are numerous and somewhat emotion driven. If I were to build two tuned loops (for the 200 - 550kHz band) as identical as possible, one made with pvc pipe for the outside frame, the other from copper (say both were 3/4" or 1" dia.), which would you recommend as the better choice and why?

Thank you.

>

I'm assuming that you would be using the PVC pipe to support a heavy-gage wire. If so, then there is a great deal of advantage in using the copper pipe, which has to do with the bulk (ie - loss) resistance of the conductor. Given two conductors made with the came material, therefore having the same conductivity and skin depth, the larger diameter material will have a greater surface area, and therefore a lower loss (or bulk) resistance.

There are two distinct advantages in having a lower loss resistance. First, with lower losses the equivalent noise temperature of the antenna will be lower, which will improve the NF of the receiving system. Since loops have significantly lower radiation resistances than most other forms of antennas, this is a significant factor.

Secondly, the lower loss resistance will equate to a lower total resistance of the antenna, which in turn will result in a higher antenna Q. For a wideband active loop this may not be an issue, but for a higher performing loop using series tuning, the higher Q of the loop using the larger conductor will result in greater selectivity at the earliest point in the receiving system, which may be an important issue when having to contend with strong adjacent signals.

Hi

I hope this does not come across as a silly question, I have a Wellbrook 1530s & 1010 both of which suffer badly from noise. Tried everything over several weeks but cannot improve reception.

Both the SDR I use and the PC have liner power supplies to reduce noise but now I am thinking can I or should I earth the loops?

Somewhat unrelated question: what minimum loop diameter one can achieve with 1" PVC pipe or copper pipe before it breaks/dents? Just curious.

That I cannot say as I have no first-hand experience bending either.
It's much easier for me to use flexible 1/4" and 1/2" copper tubing, and it's available up to 1". It's quite expensive in the larger diameters, but it's far easier to work with than rigid copper pipe. To bend copper pipe you would need a bending fixture of some sort so that it won't collapse, and PVC pipe needs to be heated in order to bend it.

Mike,
I have bent 3/4in PVC tube (electrical conduit grade, not water pipe)
to a 2ft diameter using a wooden former to suit the radius and a hair dryer
to warm the tube.
The secret is to let the tube bend naturally and not force the process
(you could put a length of plastic garden hose down to prevent kinking).
My latest loops are octagonal using 8mm dia copper tube but the bending
is the same method on a wooden former, 120 degree angle)
Good Luck,
72,Brian.

Regards to all"

Jason, If you are going to earth the loop, then you should do this at the Rx end of the feeder screen. Grounding the loop directly; say connecting the feeder screen to earth may increase the noise due to the feeder acting as a loop antenna via the mains power earth. The noise problem could be the SDR and PC; is the noise still there if you use a conventional Rx?
Alternatively the house mains wiring could be inducing conducted or radiating noise to the antenna. If the noise is mainly above say 3MHz this could be due to a nearby Power Line Transmission device used providing data over mains wiring. LFand MF noise could be due to a nearby switched mode power supply. You could try using a mains filter with an earth line choke to feed the SDR, PC and loop PSU.

Some types of linear PSU are switching regulator types, these can be noisy!!!!

Also the loop power supply could be faulty, this is not likely with Power Supplies provided to North American customers.

Kind regards

Andrew Ikin

In addition to what Andy Akin wrote you might try using some common mode chokes. I built and installed them on all my coaxes and they did help. Usually there is
no magic wand cure for noise, but several things may help. Even moving your antenna(s) may help as well. Good luck!

Chris,
Thank you for your reply. I am considering and analyzing your answer.

Perhaps I wasn't clear on the antenna question. I have already built a tuned loop antenna. It consists of a 3/4" pvc frame in an octagonal shape, 4-1/2 feet across the flats. I fed 12 turns of wire into the pvc pipe as my antenna primary with varactor diodes and additional switched capacitance paralleling the primary for tuning. I have one turn of wire within the pvc pipe as my pickup coil along with a multi-impedance matching transformer for best guess connection to the receiver. The antenna is used strictly for reception and is resonant from about 180-550kHz. The antenna works quite well. I have received over 1,100 signals in that band, mostly NDBs, NAVTEX, and DGPS.

My worst problem is, like others here, noise. Horrible noise. My question is, if I built another antenna just like the present, except I replaced the PVC pipe with 3/4" copper tubing, would the copper tubing help me get rid of some, hopefully a lot, of the noise? I know that I'm not detailing the noise problem to you, but just in general concept, would the grounded copper tubing, with an opened gap at the top, help with noise reduction?

I have read a lot of your papers, a lot of them are above me. But I feel you are contributing a lot to this group with your technical knowledge. Thank you.

Al, I think you could test the effect of the shield by wrapping your current PVC loop
with aluminum foil, with a gap at the top. Foil could be connected directly to ground,
isolated from the antenna wiring, or as Andy suggested, connected to coax shield,
which is then grounded near the receiver.

Hello Andrew
Thank you for your suggestions.
I have a 2 very quite custom built (expensive) linear power supplies that powers everything DC including my PC.
I also use several ISOL-8 units within the house.
Tried moving the Wellbrook loops around the garden, higher / lower nothing helps
Tried an earth from just before the antenna cable enters the DCblock that goes to a copper earth stake in the garden
Will dig out my old AOR 3000a and try that and will also go hunting for PLT's but would have expected to have heard those on my portables.

Kind regards

Jason

Hi Jason,

Yes, I just saw your other post. I would think the next step would be to try to determine where all the noise is coming from with a portable rx and checking
electrical devices in your home.

7997. Best Bet Loop Type Made with Surplus Cable

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-11-09 16:42:08 UTC
From: kugellagers
Topic: 7997 Message: 7997

I have about 50 +/-ft of a gray covered mil-spec looking cable with no numbering or lettering on it.

With a freshly stripped area it looks like it consists of a 12-14 gauge twisted pair of multi-strand wire wrapped in a foil shield wrapped with a 16-18 gauge bare ground wire.

Is this useful for anything loop antenna-wise? Or would I be better off using it as a shielded power cord?

It is too short to be made into a loop antenna for AM. I use about 120 feet for each loop. In addition - the larger gauge wire is shielded. A lot of conversation of this group has been about shielded loops so I just fade into the audit mode when that stuff is posted here - I've NEVER had any luck making a shielded loop. My advice is - don't even try.

For shortwave, it might be of some use, but loop antenna efficiency falls off rapidly as the frequency rises. By 30 MHz, it is probably not worth the effort.

Shielded loops are only of use under very specific conditions, as
outlined in the old RWP King book:
http://www.w8ji.com/loop_text.htm

The cable in question might make a half-decent balanced feed cable,
or a pretty good balanced microphone cable.

BTW, Bruce, your loop antenna pages have not exactly been the very
definition of availability lately. Since I recently set up a little
page on physically small antennas anyway (still learning a lot), I
adapted your JS inductance calculators for use on there.

Stephan

A similar cable but with solid conductors of about 24 guage used to
be used a lot in telecom wiring, but seems to be mostly replaced now
with tighter twisted CAT5 pair wire. I have a good supply myself of that 2-conductor with
foil and runner cable. I was thinking of trying it
for the coax downlead from loop or other antenna. I do not know the
characteristic impedance at this time of this cable. It was usually used at T1 speed data
and the usual impedance for that work is 93 ohms,
i believe. Still, a mismatch in receiving, as compared to transmitting,
is not that big a deal, and especially for moderate length runs. I was
mostly interested in learning if true balanced to ground and shielded
antenna feed wire would cut down on pickup of close-in noise.

A commentary on small loop's and an interesting loop amplifier design that includes a shielded twisted pair feeder can be found at:

http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna.htm

Certainly worth a visit for anyone interested in small receiving loops and amplifiers.

This past summer I did a number of loop and loop preamp experiments, including building the LZ1AQ loop preamp and the "crossed-parallel" loops. In his preamp I substituted transformers with more inductance to get response down to LF. I found the preamp to be noisy over the whole LF-HF range and inferior to other loop preamps I was testing. I built four 38 inch diameter loops and connected them in the "cross-parallel" configuration, and compared their performance from LF-HF to a single-turn loop of the same combined area, with the same conductor width as the C-P loops (I used the outer shield of RG-8 coax cable for all loops). At no frequency did I find the "crossed-parallel" loops with lower inductance to be superior to the single-turn loop with higher inductance, no matter which loop preamp was used. My results did not come close to matching his claimed results. I would be very interested to hear of other's results should they build the LZ1AQ loop preamp and/or the "crossed-parallel" loops, and have compared them with single-turn loops, and other loop preamps.

From: Lew
Topic: 8004 Message: 8004

Why in all the loop literature I've seen (not read every post here yet) does the capacitor in a loop antenna HAVE to be at the opposite side of the loop to the feedpoint?

I intend to make a small loop, maybe 3-4M in circumference for reception only at first but at some stage I will be using it for transmit, and I cant work out why the capacitor HAS to be at the opposite side,
WHY cant it be "at" the feedpoint?

8005. Re: Can someone explain to me

My guess is that you want to avoid high electric fields near the feedpoint. For RX-only this shouldn't be a problem. In fact, I've made a small RX-only loop with the coupling loop attached to it very close to the tuning capacitor (15-20 degrees). It works just fine.

I dismissed the "far side" capacitor years ago as they were expensive
and mechanically awkward. Instead, I devised a series of transmitting and
receive-only loop antennas that have a dual variable tuning capacitor at the
feedpoint:

Tell me about it! I am so disgusted at Mindspring - well Earthlink - if I found a decent free unlimited host I'd probably switch. The only thing holding me to them is email addresses and web pages - some of which I haven't touched in 12 years. My wife wouldn't want to change email addresses, either.

> page on physically small antennas anyway (still learning a lot), I

I don't mind as long as you credit me for the original work.

8008. wireless solution?

I have a Sony receiver for my garage. It has an intermittent static crackle across all inputs and AM radio. Some days it has it, some days not. I've determined that it only happens when the AM loop is connected. I've tried inserting solid copper ground wire in either AM terminal, and bending it over to both terminals. The crackle persists when either terminal is contacted.
Would a wireless antenna like Terk AM Advantage improve my reception at all on a unit like that? Would somehow grounding the receiver or antenna help?
My goal is to hear my local ESPN affiliate, virtually next door, and static free ipod use without having to unplug my antenna.
Any help would be appreciated.

It would have taken less time to just try grounding the ant or radio than to post this. Now that I have spanked you, it sounds like an open circuit somewhere. It probably is not a complete open but a frayed open. An example would be if the shielding strands around a cable were half torn off; that could cause a problem. I don't think it will be as simple as that though. Just try grounding it in a variety of ways. Direct to a copper rod driven into earth is my favorite way. I use 5/8" copper rod. It is expensive, but does the job. That will prove the grounding theory or show the problem is different.

I think this is not good for loops. The capacity is much to less,
you will not achieve a wide frequence range. It´s better to look for at least 375 - 1000pf types. It depends on what a frequence range you intend to reach with your loop. - sorry for my english, my tonge is german.

Unfortunately, far too low for use with loops. But, very nice for a VHF or UHF VFO.

by the way: if you´re looking for an very good loop antenna calculator, here´s a helpful link:

http://www.dl0hst.de/magnetlooprechner.htm

With this tool you can calculate by typing in the diameter of your loop antenna you intend tobuild and the capacitiy what for frequence- and frequence range, Q, bandwith and more you can estimate.
If you´re looking for appropriate variable capacitors, there´s no problem to get one, also able for transmission up to 100 Watts or more. Here in germany there is an manufacturer...

cheers Klaus

8014. RE: [loopantennas] Re: Gear Drive Ball Bearing Antique Tuning Capacitor

Yahoo group: loopantennas (2008 — 2012)

Topic: 8010 Message: 8014

The suitability of a capacitor depends, to a large extent, on how wide the frequency range you want your loop to tune.
But, the wider the range of the capacitor, the greater the pF variation per degree of plate rotation and the more difficult it is to tune accurately.
Take a capacitor with 180 degree rotation for a change of 360pF - that's 2pF per degree.
But what if the range of the capacitor was only 90pF - that's .5pF per degree - a lot easier to tune.

My loop (5.8M circumference circle - 15mm copper pipe) is used for 7MHz to 7.2MHz only.
I need a variation of only 6pF to tune all of my frequencies of interest.
If I wanted to tune to the (say) 20M band as well, I would need a capacitor with a range of 80pF.
If I was to use a 9M loop of the same material, I would need a capacitor with a range of 140pF to tune the 40M-20M bands.

I currenly use a piece of RG58 cut to length to provide coarse tuning and an 8-90pF air variable for the fine tuning.
Due to the range of the variable capacitor, I could do away with the RG58 but I will be testing the high voltage abilities of the coax.
Even with a rotation speed of 1 RPM, tuning is very fiddly. Reducing the RPM further is not an option because geartrain backlash is already significant.
I am currently building a 15-35pF variable capacitor to make tuning easier and will prune it smaller if success permits.

The other significant parameter of a capacitor is its voltage rating.
If you are going to use the loop for receiving only then just about any capacitor of the right pF range will do.
If you are going to use the loop for transmitting, you need to be aware that loops can produce VERY LARGE VOLTAGES.
100Watts into a tuned loop will produce 4KV to >7KV depending on who's paper you believe.
Either way you need a good high-voltage capacitor.

To summarise: the suitability of a variable capacitor depends on the loop itself and the use to which the loop is put.

I use loopcalc and capcalc, both available from http://www.magneticloopantenna.com.

To answer your question - in the right circumstances, yes those capacitors are OK. The range of 5-20pF would give a frequency swing of
(on their own) 2:1 and so they are not suitable for covering a wide band such the AM band but would certainly be suitable to cover a single ham band.
The plate spacing looks to be a bit wider than a "receiving" capacitor and so they might be OK in a low power transmitting loop (not the full 100Watts though).

All the best,
Ray

Hello Brian,

I think there is no english version available.
I will try to translate it. Plaese give me some time.
Currently I lay in the hospital after a heavy surgery so I have time... :-)

Yes, the calculater is very comfortable indeed ! Since I discovered
this helpful tool, it helps me a lot in developing some antennas.

I will give you a hint, when my work is done !

If you have problems to download the zip, I can send it to you. I sent it to my father too,
it was easy for him to unzip and to play around with.
If you have once the program running, it is nearly self-explaining...

stay tuned

vy 73, cheers Klaus (xcuse my english....)

Hello Brian,

after you downloaded and unzipped the file

http://www.dl0hst.de/software/magnetloop106.zip

for the calculator a mask will appaer.
I put in the mask to the photos with same translations. More is coming soon !

In this mask you can see my antenne I intend to build, 5mtr diameter !
...a giant!

cheers Klaus

8023. loop phasing ?

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-11-25 20:20:34 UTC
From: Dean Wayman
Topic: 8023 Message: 8023

After having the Pixel pro 1A up and hauling in the dx ,i have come to the place where i want to reach out even further from my listening post,I'm still getting a few new ones but it takes more time because of drift or conditions at the time.

One frustrating thing about a figure 8 pattern of a loop is having a strong station 180 degrees from a weak station,i can hear them there but the strong sig just swamps the weaker one most of the time ,i have Id'ed a few by just staying parked ,but it can be a time waster if later in the evening the weak one just goes away or another comes in over it ,and maybe i can get some stuff under my local with a phased setup.

I have been thinking about getting a second loop ,in order to get a better null and possibly do some phasing.

I already know i need a good phaser, i've been told the Quantum phaser is probably the best available right now? so my question is ?

How much distance between loops am i going to need to get the phasing too work at it's best ?

I've seen anything from 6 feet ,to a full wave so, i'm not sure now,maybe someone has a similar setup or knows the proper distance ?

Thanks for the help

How much distance between loops am i going to need to get the phasing too work at it's best ?

I've seen anything from 6 feet ,to a full wave so, i'm not sure now,maybe someone has a similar setup or knows the proper distance ?"

Dean, I assume by dx you are referring to MW dx. If so you need to keep the loop spacing to about 40-50m. This reason why this is required; Close space arrays are gain degenerative, with reduced S/N i.e. the gain drops compared to a single antenna, but the active antenna amplifier noise doesn't. Ideally one should use larger lower noise loops for this application e.g. Wellbrook ALA100 or the ALA100M with a Variable Cross-fire Phasing Unit to ensure minimal knob twiddling over the MW Band.

There is an other option; Phase your loop with a decent active whip antenna (fellow group member Steve Ratzlaff builds these). I believe the Quantum phaser will work for this application. This has the advantage of not requiring any antenna spacing. This is because there is no loss of gain. The down side is; it is much more difficult to use and requires constant phase and amplitude adjustment with small frequency changes.

Kind regards

Andrew

Thanks for the reply Andy and Steve:

I'm going to have to do some thinking on this ,the most distance i could get would be maybe 20 feet?

The vertical sounds like a good alternative if i can understand how to set it up.

Maybe Steve can post a link or email me off list with a link ,i can't seem to find info on his whip?

8027. Spiral loop question

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-11-29 21:36:23 UTC
From: Lurch
Topic: 8027 Message: 8027

Just finished the frame and winding on my MW [BCB] spiral loop. I put the one-turn coupling link on the outside. I'm wondering if it would be better on the inside or in the middle of the winding; nulls don't seem very deep up around 1500-1700 kc. Then too the rx I'm using it with, a Collins R390A, is so sensitive it can pull some semi-local and all local BCB stations up out of the noise without an antenna at all.

Has anyone here ever done q comparison of differe3nt link locations on tuned spiral loops?

Thanks in advance,
Brian KA9EGW

8028. Question answered

From: Lurch
Topic: 8028 Message: 8028

I moved the pickup link from 1 turn onte the perimeter to 2 turns inside the tank winding. Nulls on the top end are defintiely deeper.

If anyone wants to know, the crossarms are 32", windings 31.25 diagonal measure on the first turn, then 3/8 smaller on each successive turn. There are 17 turns ending up at ~10" diagonal measure.

The 2-turn pickup link is in the center at a diagnal measure of about 6" on the outer of the 2 turns.

Not bad for a couple hours work--an hour before nominal local sunset I had broadcast-quality copy on WSM 650 AM from greater Beloit, WI...and IIRC we're almost in one of WSM's pattern nulls.

Now to get all the tube shields, drill bits, test equipment, toolboxes, etc out of the loop's near field LOL.

My bad--the innermost tank winding is 19.25 diagonal measure, half of that is ~10". I'll try to post a pic after I get the base built.

Hi Greg,
Perhaps you need a better LF antenna. All North American Loran activity has ceased, but I can get the remaining Asian Loran stations most any morning around sunrise. I can easily audibly hear the familiar Loran "clatter" too then; sometimes it's even strong enough to show on the S meter and usually lasts for an hour or more. COAA has a nice decoder for 100kc Loran that I use to verify the chain I'm receiving.

The base mount is a 'yet' project. The first loop I built, in '78, I used a piece of 1x8 on the bottom, 2 pieces of 1x4 up the sides and a piece of 1x4 across the top and bored a hole all the way through the top piece and halfway through the bottom piece. It worked quite well until I got rid of that loop for other reasons not related to it's functionality.

Spiral loops don't have to deal with azimuth-tilt unbalance...

If I don't go that route again, PVC pipe should offer possibilities...but finding flanges for plastic pipe locally is a challenge, mcmaster dot com has them...at close to $10 each. I already have plenty of scrap wood to build a base from.

Some people use camera tripods or tv-antenna roof mounting tripods.

I'd just take my 2x8 base and 3 or 4 table legs if I were going that route. You know the kind? They screw into a plate that screws to the bottom of the table, and if you get the right kind of plate the legs splay out ~5 degrees. I think you can buy 'em at the big-box stores.

I went to the auction site and found a 1" PVC 5 way [4 out, one up] for $3.60 plus $1.99 shipping. Minimum qty 1. The seller, formufit, has others as well. No connection, we'll see how fast it gets here.

Hmm...my mama named me Brian, my biker friends call me "Lurch".

Anyway, I knocked together a base for mine in about an hour this afternoon. Just a foot of 1x8 and 3 pieces of a deck board left over from the deck. The frame of the loop is 3/4 square stock, so a 1" brace and bit [thanks, Grandpa] and a bit of sandpaper work chamfering the corners of the frame stock about 1/16" and all I have left to do is wait for the right variable cap to arrive [one with tapped holes on the bottom; the current stud-mount cap works but isn't amenable to decent mounting] and I'm off and running.

"Work good, last long time".

Let me know if you need a pic.

8042. FS variable caps

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-12-01 00:14:24 UTC
From: Lurch
Topic: 8042 Message: 8042

Now that my loop project is dialing in, time to clear the clutter off the workbench. I have several variable caps surplus to my needs. One is a 2-section, looks like 365pf MOL per section, with a reduction drive, with 3 studs hanging out the bottom for mounting. Two more are single-hole panel mount with a 3/8-24 threaded bushing--I suspect maybe came from an MFJ-901 antenna tuner, if so then they're supposed to be 10-324pf apiece but I'm not positive that's where they came from. They came out of a $5 homebrew antenna tuner I bought years ago at a hamfest, and I suspect an MFJ-901 or the like was cannibalized to build it; the only markings on them are "KAAR ENG CO" on the ceramic endplates.

I'm asking $12 each shipped CONUS or $30 for all 3. Please reply off-list to ka9egw[at]britewerkz[dot]com

8043. Faraday Loop Questions

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-12-02 18:47:04 UTC
From: Neil
Topic: 8043 Message: 8043

I have a few questions regarding the Faraday loop method of feeding a magnetic loop antenna.

1. I understand that the loop needs to be about 1/5 of the diameter of the main loop. What is the theory behind this?

2. What are the advantages of using a Faraday loop over a simple loop of wire?

3. Does the feed point of the Faraday loop need to be adjacent to the main loop? Does it make any difference if the feeder connection is towards the centre of the main loop?

8044. Band Pass filter for Medium Wave band

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-12-02 19:09:46 UTC
From: notareallyreal
Topic: 8044 Message: 8044

Hello !
Has anyone experience on band pass filters for Medium Wave band ?
I think that some times very strong local transmitter can spoil your whole medium wave band, even if it was outside the MW band.
To minimize strong noise/interference from outside of medium wave band I have thought to build a band pass filter. I think that it would help also for other kind of local noise source.
Cut off frequencies could be about 530kHz and 1700 kHz.
Some attenuation in MW band is not a problem nowadays because there is lot of amplifier solutions available.
BR

I just downloaded the Ham filter design program Elsie to the files section.

Download it, install it, and have a blast making all kinds of LC filters.

Dave

Subject: [loopantennas] Band Pass filter for Medium Wave band

Hello !
Has anyone experience on band pass filters for Medium Wave band ?
I think that some times very strong local transmitter can spoil your whole medium wave band, even if it was outside the MW band.
To minimize strong noise/interference from outside of medium wave band I have thought to build a band pass filter. I think that it would help also for other kind of local noise source.
Cut off frequencies could be about 530kHz and 1700 kHz.
Some attenuation in MW band is not a problem nowadays because there is lot of amplifier solutions available.

1. Impedance
2. The Faradays loop only picks up the current in the tuned loop (i.e. primary the loops tuned frequency all others are more shielded).
3. Simplified answer, the same as nr.1

PS English is my third language (after Norwegian and Thai)

Now that is a combination of language competency that I would not anticipate. Norwegian and English yes, but how did you end up being competent in Thai?

Has anyone ever tried using a roll of copper flashing to make a loop? I've been thinking about using PVC pipe to make the loop then wrapping the flashing around it. I figure I could make a fairly large diameter conductor this way for transmitting but:
Would the PVC have any adverse effects?

Steve,
Before you commit expensive copper flashing to the loop project
try cooking foil (in the UK the Turkey grade is heavier).
I wrapped a 2 in dia PVC TUBE (white) as a 20m rotary dipole indoors
and it worked fine with my TS-130V, 5 watt rig.

Steve,
I omitted to add that I have also replicated the foil antenna project
by rolling the foil lengthways and feeding it down the inside of the tube,
this would be much better for outdoor use of course.

Hi Steve,

The conductivty of various metals can be much less than pure copper. It does not take much impurity to drop an alloy down to 50% of the conductivity of pure copper. Which is much worse than pure aluminum. I am not sure of the alloy of copper flashing. But, I think it is an alloy (either on purpose of through lack of refinement), as its quite stiff material, and pure copper is not as stiff.

GA Copper sells materials for grounding. They are quite expensive. I am wondering of they are selling the oxygen free electrolytically refined copper. Which is the standard on which IACS conductivity is based.

If you can get un-alloyed aluminum, and your antenna does not require any joints, this would be very good.

IE, you do not want to attach the foil to a capacitor, but make a capacitor out of overlaping extensions of the foil.

Also, there is no need to join the metal to make a complete tube of metal over the PVC. Just make an U shape cross section on the tube, with the bottom of the U towards the inside of the loop, and fasten the metal to the tube in a non-conductive fashion (glue, tape, and then paint over with TiO2 pigement paint - WHITE).

Covering PVC 45 joints could be a problem. I have seen some PVC formed into perfect bends, but usually not a complete circle. I imagine it can be done, but would be custom.

Graham
Thanks for the information. I looked at his slug tape antenna and now I wonder if anyone has tried a helical loop. One could make the loop from PVC and wrap it with slug tape. This would increase the inductance of the loop and allow for a lower C tuning capacitor yet the wide width of the tape would keep resistance to a lower value compared to wire.
So far I've only seen slug tape available in 15 ft. rolls which is a little short and a joint would create unwanted resistance. Maybe it can be purchased in bulk somewhere.

Steve and Brian,
Cooking foil does have the disadvantage for a loop of having a higher electrical resistance. I have found copper tape of the sort sold here as slug tape (and also as shielding in electrical guitars) to be effective and physically light. It can be threaded double through white pvc pipe so it is maintained in a circular or rectangular shape, is less likely to tarnish and can withstand some light rain. My impression is that the pvc is no problem at QRP power levels at H.F. John G0UCP

There is a copper foil with an adhesive backing available called "Slug Tape". Apparently slugs don't care for copper and you would put this around your garden plants you don't what the slugs to get at.

I stumbled across a web site a couple of webs ago which made reference to this material and it's use in making an antenna:

http://cqhq.wordpress.com/2010/11/20/m6akvs-variation-of-the-rybakov-antenna/ with a reference link to another site with a bit more information.

And further discussion here:

http://forums.qrz.com/showthread.php?p=2098711

Seems like a good idea, perhaps a bit fragile for a portable collapsible antenna but the idea may be suited for a more or less permanent installation. I have tucked the idea away for further exploration at a later date; I was in fact thinking of a loop antenna of some sort.

cheers, Graham ve3gtc

From: neilbellgroups
Topic: 8058 Message: 8058

This is a mint condition Quantum Phaser, includes the AC power adapter, and a D-Cell battery power pack that allows operation in the field where no AC power is available. The Phaser sells for $135, The AC adapter sells for $10.00 and the battery pack is $15.00. Total cost was $160.

Best offer over 90.00 by Friday Dec 10th gets the whole package and I will pay shipping by Priority Mail to any USA address. Canadian offers will be entertained but shipping will be extra. Contact me by e-mail PLEASE, not on the group list! If no sale by Friday I will put it up on e-Bay.

see: http://dxtools.com/PRODUCTS.htm for additional info. The unit works perfectly and is in excellent cosmetic shape.

Check my e-Bay feedback - it is 100% positive - user name is "neilbell"

Yes Brian it is self-adhesive, but when used inside PVC pipe it is easier to handle
if the shiny paper backing is left on. I described a way of using this, together with a

method of feeding the loop with a variable inductance coupler in the Sept/Oct issue

of 'QEX'. Recently I have used blue flexible 20mm 'polypipe' instead of white PVC.
Incidentally it is hard enough to guess the effect of skin and edge effect on these
 tapes. I would tend to avoid serrated edges! 73 John G0UCP

Slug tape with a serrated edge.

That is interesting. Perhaps an easy way to make the antenna more broadband?

I have just recently started to read a bit on the topic of fractal antennas and this sort of, kind of, sounds similar. So many interesting ideas, so little time to try them all.

Cheers, Graham ve3gtc

Paul Cianciolo, W1VLF is a very useful resource when it comes to highpass, lowpass, and bandpass filters. He builds and sells very high quality units. If you need specific cut-off frequency values, Paul's the Man.
I was very pleased with the custom filters he built for me 3+ years ago when I was optimizing BCB image rejection in a Flex-Radio SDR-1000 receiver. I used three, switched lowpass filters in the SDR and I couldn't have built them myself with the quality and testing Paul did. He even provided spectrum analyzer photos showing the exact responses of the filters he supplied.
Here is Paul's web site:
http://www.rescueelectronics.com/RF_Filters.html
<http://www.rescueelectronics.com/RF_Filters.html>
You can see the filters he built for me in this photo of the highly modified SDR-1000 I constructed; look for the stacked trio of aluminum enclosures at the bottom with "W1VLF"

From: John McKee
Topic: 8063 Message: 8063

Hi everyone,

Just recently joined this group and was wondering if anyone has built the active receive loop by Des, M0AYF? I wanted a small low noise loop primarily for the lower end of the HF band and maybe a bit of MF listening. The amplifier part is complete and all I need is to finish wiring the bias tee. I used 2N2222As in a TO18 case with push on heat sinks in place of the BC337s. Not quite sure what to expect. I powered up the amp with a 12V supply and checked voltages and supply current. That part looks ok. Hope to get it up in the air this weekend.

Thanks,

John McKee

Yes, that's it. I've seen this design many times. Quite simple and fairly popular.

Chris

Philip - maximum pickup will be along the plane (edge) of the loop with minimum pickup broadside (facing) the loop.

> Which is the strongest reception direction of a circular loop...

That depends.

For a full size one-wavelength loop, maximum is perpendicular
(broadside) to the loop, with no signal in the plane of the loop.

For an electrically small loop (much less than a wavelength in
circumference), maximum is in the plane of the loop with no signal
broadside to the loop ... exactly the opposite.

For a loop that is much larger than one wavelength, maximum signal
tends to tilt over *towards* edgewise again, but never reaching it.
For practical large loops, the maximum tends to be somewhere in the
middle between edgewise and broadside.

And of course you have interaction with the ground and other objects nearby.

Andy

And, that assumes ground wave, as the pattern may be different - at
least for small loops - when the arrival angle is well above the horizon.

That's interesting...

My loop will be an untuned but amplified single turn loop
of about 2 meters diameter so it looks like edge on to the
source will be best then, given it will be used for HF bands?

Topic: 8063 Message: 8076

Hi John and the group,

Firstly, my thanks for your interest in the active loop antenna and for bringing to my attention the fact that the M0AYF web pages had become lost in cyberspace. It seems that thersgb.net is having major problems of some kind. The Google cache shows the pages as still active on 23rd Nov 2010 03:41:13 GMT so the failure must have happened between then and now.

So for John and anyone else who is interested in the active loop antenna I have uploaded the pages to QSL.net and the URL is as follows...

http://www.qsl.net/m0ayf/active-loop-receiving-antenna.html

The general "theme" of the web pages is dedicated to QRSS of which the loop antenna was a small part. The general URL for the entire web site is...

http://www.qsl.net/m0ayf/

Thankyou again for your interest and good luck with your active loop experiments.

73,s to all and best wishes for the Christmas season.

Des (M0AYF)

8080. 9:1 transformer

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-12-12 14:47:01 UTC
From: Steve Ellington
Topic: 8080 Message: 8080

Why are people using 9:1 transformer on small loop antennas? The loop just posted by W1AEX is nice but we know the loops impedance on the BCB and 160m would be but a fraction of an ohm. The 9:1 ratio transformer would step this down even further and present an even poorer match to the 75 ohm coax! EZNEC computes an 85' loop's impedance at 1 mHz to be 0.0001839 + J 269.9 ohms. If anything, I would have reversed the transformer in an attempt to step up the loops impedance although that would be of little help since the Z is already a virtual short circuit.
Maybe I'm missing some secret formula here. Can someone shed some light on this?

Turn the transformer around so that it's 1:9. It's generally understood that it is used this way.

Steve, the way I see it; 85 feet is a large loop with a relatively high impedance or reactance Z, only the Resistance is a virtual short. Therefore, it seems logical to use a step down transformer. I have done this in the past with modified K9AY antenna and it works quite well. A 9:1 ratio seems to be reasonable compromise for the intended Freq. range. For BCB use one could use say a 4:1 ratio.

Hi Don,

Well, if you are interested Dxing NDB/DGPS/Navtex there are lot's of them out there but they are going away. There were two active ham Lowfer's in the LA area but one moved to Louisiana and the other has been off the air for a few years it seems.

As you are just starting out and to keep it cheap and tweek your interest - I would recommend a vertical wire loop as big as you can make it (unamplified) - probably in a rectangle shape orientated E-W - and assumming you are putting it outdoors.

As you can see below I have several amplified antennas for LF - two of them are loops. The ALA-100 is a single wire loop fixed E-W 88ft circumference, LFL-1010 a 3ft dia loop on a rotator. I'm on a small lot and these work out terrific for me. I plan to put up another ALA-100 N-S soon. I've logged nearly 1000 NDB's from Japan to Australia to Brazil to Alaska to eastern Canada.

Anyway, NDB's in the LA area you should be able to easily pick up with just about any simple antenna (in AM mode or ~+1kHz in SSB/CW):

233 LG Long Beach Apt
253 UR Burbank Apt
337 NA John Wayne Apt
370 PAI Whiteman Apt
378 CPM Compton Apt
397 SB San Bernardino

At night there are lots more of course. Some easy nightly regulars:

205 COR Corcoran
209 HGT Hunter Liggett
282 GWF Lancaster
332 POA Hawaii Island
338 PBT Red Bluff
338 RYN Tucson
344 FCH Fresno
351 NO Reno/Tahoe
353 LLD Lanai Island
394 ENZ Nogales
404 MOG Montegue
408 MW Moses Lake
521 INE Missoula
526 RWE Camp Roberts

Another Don in the LA area,

Don

8085. RE: [loopantennas] 9:1 transformer

Yahoo group: loopantennas (2008 — 2012)
Date: 2010-12-13 00:19:36 UTC
From: Ray Phillips
Topic: 8080 Message: 8085

Steve,

To get the best results from a loop, the loop impedance and the feed line impedance should be as close as possible.

At RF frequencies, a loop is essentially a high impedance device. If a loop is heavily loaded by a low impedance feed line, its efficiency is reduced and loop performance is compromised.

The resistive portion of the impedance of your 85' loop at 1MHz is so low that we can ignore it.
If you were to present the loop with a feed line load of 75 ohms, this load is much less than the J 269.9 ohms and you would not get a good transfer of signal.
A 9:1 transformer will take the 75 ohms of the feed line and transform it to 675 ohms. A 4:1 would give 300 ohms which is a closer match to the J 269.9.

However, as in most things antenna, there needs to be a compromise.
To choose a transformer, you need to calculate the impedance of the loop at the low frequency end of frequencies of interest and at the high frequency end and select a transformer ratio which is the "best fit".

Another solution (for 50 ohm feed line) is to make a "pick up" loop one fifth the size of the main loop and place it close to one side of the main loop (bottom recommended). Connect this to the feed line.
Join the two ends of the main loop together. The length ratio between the main and pick up loops performs the transformer function. At first glance the ratio appears to be a high 25:1 but operational use suggests that one fifth is the way to go. For 75 ohm feed line, the ratio would be different. I don't use 75 ohm cable and cannot offer any experience but the maths suggests one quarter main loop size.

I recommend using a "Faraday" style pick up loop which uses coax in a special configuration.
http://combotec.com/projects/magloop-HF/magloop.html
http://homepage.ntlworld.com/g4kki.william/LOOP.PDF

All said, the main rule of thumb for antennas is "Experiment, experiment, experiment".

From: n4lq
Topic: 8080 Message: 8086

I am so accustomed to first canceling out the reactance then matching the antenna. It's a ham radio habit I suppose. If you cancel the 269 ohm reactance, you're left with an impedance of nearly zero. Matching this would require something a bit more than a 9:1 transformer.

A 1 wavelength loop for 160 meters is over 500 feet in circumference. Normally when hams refer to a loop shorter than 1 wavelength it's considered a short loop. A 1 wavelength loop has an impedance of about 100 ohms so a 2:1 ratio transformer would make a good match.

So these little 85 ft. loops are really short by these standards and considerable series capacitance is needed to cancel the reactance. As you stated, matching could be done by the 1/5 cir. loop or by a gamma match. Bandwidth would be very narrow and constant retuning required as frequency is changed.

Looking again at this 85 foot loop when used at 1 mHz.....Yes we are dealing with J269 or there about but what about that 9:1 transformer. Everyone is assuming the transformer somehow converts this reactive load into a 75 ohm resistive load to match the coax however I see no technical reason why it would work.

The designer of this antenna mentioned a 20db loss compared to a dipole. The huge mismatch is probably why. Noise seem lower simply because it is much weaker. I believe the (matching system) is actually acting as an attenuator, dropping the noise level below the receivers internal noise and giving the illusion of a "low noise antenna". Possibly the same thing could be done with some resistors in line with the dipole.

Anyway, I've seen many antenna articles using these magic magnetic 9:1 transformers and I believe much of it might qualify as urban legend.

Thanks all for your comments. 73

The 9:1 ratio transformer would step this down even further and present an even poorer match to the 75 ohm coax! EZNEC computes an 85' loop's impedance at 1 mHz to be 0.0001839 + J 269.9 ohms. If anything, I would have reversed the transformer in an attempt to step up the loops impedance although that would be of little help since the Z is already a virtual short circuit.

>
>
>
> Steve, the way I see it; 85 feet is a large loop with a relatively high impedance or reactance Z, only the Resistance is a virtual short. Therefore, it seems logical to use a step down transformer. I have done this in the past with modified K9AY antenna and it works quite well. A 9:1 ratio seems to be reasonable compromise for the intended Freq. range. For BCB use one could use say a 4:1 ratio.

The good Moebius has been quoted a lot in connection with loop
antennas. I have yet be convinced that his theory has anything to
do with antenna performance. But thanks for the reference. John G0UCP

John,
With our inclement weather workshop activity on antennas has been halted hi!
On this site there is an interesting item in flexible copper tape but with both
sides insulated from each other.

www.die-wuestens.de/eindex.htm

It might be useful for a Mobius type loop ????

From: brian nsl
Topic: 8088 Message: 8088

John,
Thank you for the comments.
The Mobius guy certainly has an impressive background, in NASA activity at least hi!
I consider it mainly a space saving idea i.e. two turns in the space of one.
When the weather improves for workshop activity I want to try a multi turn Mobius,
say 4 core cable in an 8mm copper tube loop, in theory a 5 turn loop in the space
of one say 2ft diameter !!!!!
Indoors I am playing with making an antenna for a Denon DAB hi fi unit I bought
last week, there is no way I can nail the dipole supplied to the lounge wall hi!
Regards,
72, Brian.

That won't result in a Moebius loop. The shield/conductor interconnections get a little bizarre after two turns. The 2-turn Moebius loop is described in the tutorial I added to the files section about a year ago, "Shielded Loop Aerials Rev 0.pdf".

Chris,
Yes, I have your excellent article on the subject to hand for reference.
In my idea there would be no ' interconnections ' it would in effect be just a length of wire within the copper tubing.
Though I did say ' 4 core cable ' I could achieve the same result with one long length of wire fed thought X times, the two ends connected to the tubing at the top and the loop feed taken off the bottom tube ends.
There are lots of ' ideas ' in my scrap bin hi!

Not sure what your arrangement would result in. If I've mapped it correctly, you would have Vs(X+1) times the voltage at the terminals, and I think the terminal current will be Is/(1+X), where Vs and Is are the shield outer surface voltage and current. That would result in a terminal impedance of Rs(1+X)*(1+X) where Rs would be the terminal impedance of a non-shielded loop.

It will be interesting to see the results of what you have proposed. I've liked the idea of the simple Moebius loop (ie - X=1) as if uses no more material than a "regular" shielded loop and results in a 4:1 impedance transformer, which eliminates the first transformer in my series matching networks, hence slightly better performance and less cost.

And an understandable one, too - otherwise radiation efficiency would be extremely lousy, and hams want to be heard. It's not a bad idea for reception purposes either, though the requirements are a lot more relaxed due to all the atmospheric, galactic and man-nade noise picked up by the antenna plus usually good receiver sensitivity. My big loop with AR7030 won't hear any more on 160m than my ICF-SW7600G (forced to use the ferrite rod) with the little 9" Tecsun AN-200.

> If you cancel the 269 ohm reactance, you're left with an
> impedance of nearly zero.

Depends on how you do it. A series capacitor would do as you say, a parallel one would yield a very high impedance (of (wL)^2/R). But in any case,

> Matching this would require something a bit more than a 9:1
> transformer.

I use a pickup winding with a 27 cm base length (total length ~70 cm) on a 4-turn 93 x 93 cm box loop, which seems to give a decent match to 50 ohms on 80m up and still is OK for 160 and upper MW. It is important to run the pickup wire in parallel to the wires with the highest current (and as close as possible), usually opposite the varicap. Those with the least detuning when touching them are correct.

Speaking of pickup loops, they are entirely non-critical electrically. Their resistance only has to be small vs. transformed impedance (~= receiver input impedance), which is dead easy. Main loop loss resistance should be small vs. radiation resistance, with the latter only being a fraction of an ohm on most reasonably-sized loops.
Therefore, you can pretty much use whatever seems most practical for the pickup loop, as long as it's reasonably conductive. A piece of wire may be more useful on a wire loop, while a piece of coax shield might give better coupling with a tubing loop.

> So these little 85 ft. loops are really short by these
> standards and considerable series capacitance is needed
> to cancel the reactance. As you stated, matching could be

> done by the 1/5 cir. loop or by a gamma match. Bandwidth
> would be very narrow and constant retuning required as
> frequency is changed.

That's the price to pay for a physically small antenna if
any kind of radiation efficiency is desired. The sharper the
peaking, the higher the maximum signal level.

> The designer of this antenna mentioned a 20db loss compared to
> a dipole. The huge mismatch is probably why.

20 dB isn't even *that* bad. For my big loop, RJELOOP3 [1]
calculates about 38 dB below 1/4-wave vertical at 1540 kHz
to 21 dB at 4800 kHz. Obviously you wouldn't want to use
that one for transmitting, but it'll easily hear into the
noise. On 160m, the AR7030 shows S5 of noise with 10 dB
preamp on, 80 expectedly is quieter. I rarely get anything
more than S9+10 on ham stations even when others attest 20
to 30 over, so 20 to 30 dB below fullsize is realistic.

In order to achieve any kind of radiation efficiency on
160 with a physically small loop, you really need to jump
through some hoops (pun not intended). About 20 m of 4"
copper tubing and a 500 pF / 10 kV varicap could come in
handy. It all gets a lot more relaxed if you only need 20
and higher.

Stephan

[1] I had to use DOSBox (the emulator) or it wouldn't run.

You can either series resonate or parallel resonate the reactance.
You either end up with below 1 ohm or up in the 1000's of ohms.
As I showed in my National Contest Journal article (available from
ARRL or my web site www.n6rk.com), it is entirely practical to
match 5000 ohms to 50 ohms using a 10:1 turns ratio. Attempting
to match milliohms to 50 ohms would likely run into leakage
inductance limitations and in any event would not be amenable
to varactor tuning (too much capacitance is needed). The effective
series resistance of the loop is almost entirely the copper loss
of the conductor, since the radiation resistance is so small.

I let Grouply make automatic backups of my groups. Unfortunately they do not back up the files, links, or database sections. But they do back up the message archive, photo, and calendar. There is a lot of controversy about Grouply - and you have to be extremely careful in what you click or they will spam all of your member list with Grouply invitations.

Still - with all the problems - their business model is to vigorously mirror groups on Yahoo and Google, which is to the advantage of anybody concerned that an entire group with its irreplaceable message archive disappear the way Geocities did.

From: uvucpnite@ymail.com
Topic: 8103 Message: 8103

Hello: I recently installed what is called a "Super Loop" 80-10 meter (inverted triangle) vertical delta loop antenna with the apex (feedpoint) pointed down. The upper two ends of the loop are 60 feet high and the lower feed point (apex) comes down at an angle to about 20 feet high. Would it be be best to let the apex hang down vertically from the horizontal part of the loop to maintain it's vertical integrity? It seems to work well as is on stateside contacts and it doesn't do too bad on DX either. The articles I have read on this antenna are not clear (at least to me) on the exact position of the apex (feedpoint). Thanks!

You are fine with your wire loop set at vertical, horizontal, or somewhere in between. For 80m Dx vertical is best. To bend S meter needles over a 300 mile radius, horizontal is more likely the way to set up. You will soon find out about your antenna's performance as it is set up now. If you use it horizontally, although performance on 80m will be great over a 300 mile radius, it will throw out very low angle lobes on 20-17-15-12 and 10m for Dx performance. After dark, the f1 and f2 layers converge at useful height above earth to work 1000 miles plus with ease on 80m.
I hope this quick thumb-nail sketch is a helpful indication of what to expect. Good luck.

You need 3 antennas. One for the AM broadcast band. One for Short Wave and one for FM.

Where do you live and what are you trying to receive?

It sounds like you are using a really crummy radio to begin with.

For AM you can buy a small loop that sets next to your radio. It will greatly help with distant reception. Here's one. All you do is set it next to your radio and tune the one knob for maximum signal.
http://tech.pronto.com/mpm/compare/kaito-an200-tunable-am-passive-10306411476

For FM and short wave your radio needs to have an external antenna input. Does it?

Short wave reception can be improved by simply hooking a wire to the radio's antenna jack (if it has one). The wire can run around the room, out the window or whatever.

FM is more demanding. You really need a beam type antenna. I would guess your radio doesn't have an antenna jack.

hi i new to the loop so i just tell you why am here looking at making a loop for my solar powered radio it just a am/fm / shortwave i live on a little hill out in the sticks ,just like to get a better signal from my radio . it will do ever thing i need once i can pull in a better signal
1/ so can a build a 1 loop that am/fm and shortwave [thinking may be not]
2/ can i build 1 loop that dos say am/fm then put a 2nd loop cross-ways to the 1st loop to do shortwave [has this been done before?]

i am going to look at the files you have here see what you have
but any help be great building a loop look mostly simple as long as you get the sizes right
thank you for all yr help
paul
ps please keep everthing in english ahhahahhahahha i not a techie

The "Super Loop" is a product of Radio Works. Is this what you have? If so, it was designed to be installed vertically.

I'm seeing answers that are all over the map here. Super Loop is a brand name. If you just made a loop of your own with no phasing line across the middle the the rules change.

Subject: [loopantennas] SUPER LOOP ANTENNA QUESTION

Hello: I recently installed what is called a "Super Loop" 80-10 meter (inverted triangle) vertical delta loop antenna with the apex (feedpoint) pointed down. The upper two ends of the loop are 60 feet high and the lower feed point (apex) comes down at an angle to about 20 feet high. Would it be be best to let the apex hang down vertically from the horizontal part of the loop to maintain it's vertical integrity? It seems to work well as is on stateside contacts and it doesn't do too bad on DX either. The articles I have read on this antenna are not clear (at least to me) on the exact position of the apex (feedpoint). Thanks!

Look at "ferrite rod antenna" on Youtube video for an interesting alternative to the air core loop designs.

Hi Paul W,
Make sure you tell the loved one who bought this device, that it is not just "crummy", but REALLY crummy.

Steve is correct, that in a more prefect world, 3 antennas would be useful. But a more detailed explanation (what radio is it, does it have provisions for multiple antennas, what stations do you listen to, are there any adjacent channel stations that cause interference, etc.) would allow members to better help with a solution(s).

Even inexpensive radios can be improved with the right antenna. But a single "do all" antenna is a difficult solution depending on your detailed situation.

Enjoy your radio, for it is much better than have no radio at all. The magic of radio is never lost on me.

M Holden: Very good information on my vertical loop. I've now tried it vertically and a few places in between vertical and horizontal. It seems to work about the same either way on transmit, however it does appear to capture more 80 meter dx on receive vertically. Thanks.

--- In loopantennas@yahoogroups.com, M HOLDEN <mholden909@...> wrote:
>
> You are fine with your wire loop set at vertical, horizontal, or somewhere in between. For 80m Dx vertical is best. To bend S meter needles over a 300 mile radius, horizontal is more likely the way to set up. You will soon find out about your antenna's performance as it is set up now. If you use it horizontally, although performance on 80m will be great over a 300 mile radius, it will throw out very low angle lobes on 20-17-15-12 and 10m for Dx performance. After dark, the f1 and f2 layers converge at useful height above earth to work 1000 miles plus with ease on 80m.

Hi,
For a number of years I ran a reflector loop under my 40m full wave horizontal one.
The driven element was at 35ft and the reflector loop 17ft below it, appx 0.125 wavelength.
Operating consistently with 5 watts SSB it did appear to benefit operation.
From regular contacts a consistent comment was that my signals were not affected by
QSB as much, though I never quite figured that one out hi!
Why did I remove the reflector, house painting one summer and just never put it back !!!!!
Discussing the subject with the late L B Cebik, his conclusion was it was hardly worth the
hassle of erecting it.

Yes, there is a noticeable gain, but only on the fundamental design frequency, not on the harmonically related ones. It is a 2 ele quad shooting upwards. Mike G4HOL

I think that would actually be considered a ground plane rather than a reflector. It may be of some assistance for a loop mounted high off the ground or on 'real' ground that is lossy due to factors you can't control (location specific and rare). If you have the loop up high, I'd try setting it up temporarily on real ground and see if it seems to help the performance and/or noise. If it does then making an artificial ground plane for your usual mount position up high should benefit. If you don't see a difference I wouldn't waste my time.

> I think that would actually be considered a ground plane rather than a reflector.

Just curious ... why do you say that? In your eye, what is the
difference between a ground plane and a reflector?

Me, I'd call it a reflector if it is a wire loop under the radiating
loop. If it is a solid sheet of metal, or a wire mesh that extends
well beyond the circumference of the loop, then I'd call it a ground
plane.

Many people who do NVIS find a marked improvement when they lay a
reflector wire or two underneath their dipole, either on or a few
inches above the ground. It might not help everywhere, but enough
people have said that it helps, that I think there must be something
to it. At least one person put a knife switch in the middle of his
reflector wire, so he could see just how much improvement it makes.

Your results may vary depending on frequency, on dimensions (size and
spacing), on distance from ground, and on your particular soil
conditions. The latter might not model very accurately in EZNEC.

Andy

Joey: I hope you are talking about a horizontal loop. Everyone seems to think you are but you might be talking about a little magnetic loop or something. Who knows.

I had a 160 meter, full wave, loop up 60 feet and I put a reflector under it. The reflector was about 6 feet off the ground. Basically I had a cubical quad aimed straight up. I tried making the reflector 5% longer than the driven element.
I could tell no difference on 160 meters but really....The only way to measure gain would be to fly above the antenna in a helicopter and use a very sensitive field strength meter. For a number of reasons, the reflector would not function on harmonics but especially since the loop no longer acted as an NVIS antenna.
Bottom line: The reflector was a waste of time.

Subject: [loopantennas] Loop reflector

what has anyone experienced using a reflector under the loop they operate on? Is there a real increase in gain?

If it's horizontal then it's omnidirectional so it definitely wouldn't qualify as a reflector which implies a directional antenna. Well maybe directional straight up but I'm not sure what good that would do a guy

A horizontal 1 wavelength loop, if up sufficently high, has a radiation pattern almost identical to a half wave dipole- that is a figure 8 pattern.

Dale W4OP

If it's horizontal then it's omnidirectional so it definitely wouldn't qualify as a reflector which implies a directional antenna. Well maybe directional straight up but I'm not sure what good that would do a guy

Yep....Straight up is exactly what I meant. A reflector under a horizontal loop does the same thing as the earth but with slightly less loss. The ultimate reflector would be solid copper under the loop.

I remember reading an article in a British publication concerning a cubicle quad antenna. Seems that a storm had bent the mast and the quad became horizontal. The author reported that many signals were stronger and surmised that many signals, even on 20 meters, arrive at very high angles.

Non-directional in 2 dimensions does not mean non-directional in 3 dimensions. A cubical quad is a directional antenna no matter how you orient it, as long as you are looking at it in 3D.

Horizontal full-wave loops are quite useful, for NVIS and high angle communications, which many hams use without realizing it. Yes, cloud-burners are actually important, on the lower HF frequencies, for regional coverage. Generally not so much for DX. (Which is not to say that horizontal loops can't also work for DX, on higher freqs.)

Where did you hear that?

A full wavelength loop, in free space, has a pattern that looks like a dumbbell: two major lobes in opposite directions (perpendicular to the loop), and a null going a full 360 degrees around it in the plane of the loop.

A half wave dipole has a pattern like a donut, which is almost exactly the opposite.

So I'm trying to figure out what orientations of the loop and of the dipole you are envisioning.

Most half wave wire dipoles are horizontal, and tend to have maximum signal broadside to the wire, and nulls off the ends (except for interaction with the earth or ionospheric reflections). A full wave loop at any height is essentially nondirectional with respect to its axis. Its primary radiation is straight up and straight down, so it makes a good antenna for high angle signals; though if you mount it a half wave above earth, it may get a null going straight up due to cancellation with its reflection.

I didn't hear it, I modeled it with EZNEC. Think of a 1 wavelength horizontal loop as two half wave dipoles spaced 1/4 wavelength apart- it is obvious this is not omni and will have classic construction and destruction azimuth pattern.

OK ... but now think of it as four shortened (quarter wave) dipoles in a square.

Now it's not so obvious that it might have classic dipole radiation
characteristics.

Thinking that a loop is like two dipoles in parallel, is a real stretch.

And in fact a good 1 wavelength loop radiates nothing like a dipole!

Bend a circular loop into a square or triangle, and it's not quite so
omni anymore; but it's still close enough for government work.

Andy

You cannot think of it as 4 1/4 wave dipoles as there are only 2 current loops.
Model the antenna with any of the popular software ad we can end this disagreement.
The models converge very nicely and do not disobey any of the miniNEC limitations.

Andy;
I'm glad you spoke up.
Here is a link to an Eznec model of an 80m horizontal loop. I've never heard anyone claim a loop had the same pattern as a dipole until now.
At typical heights, this loop has a circular pattern and vertical radiation is straight up. At greater, 1/2 wavelength, heights the pattern will show a bit of a bulge opposite the feedpoint and a lower angle. Of course the pattern changes for the harmonics but never the same as a dipole. It's a great multiband antenna and very common.

Hi Steve,
That loop is virtually on the ground at 1/8 wavelength- any horizontal antenna that low is going to be an omni. Also look at the elevation slice angle -90 degrees.

My statement said "of sufficient height".
Do you want me to send you the EZNEC wirelist of a full wave loop in free space vs a dipole in free space- the patterns are almost identical.

I have seen the article before- but LB does not address the high loop- only NVIS applications at the loop's fundamental frequency..

Some years back I was presenting a paper at a regional VHF/UHF conference. LB was there and we had lunch together on the first day of the conference.As we ate, I was glancing through the Proceedings and noticed a paper on 1 wavelength "omni" horizontal loops for VHF and UHF. I mentioned this to LB and my doubts that these were omni at all.
LB glanced up at the ceiling and after a minute of silence pronounced that indeed these antennas would not be an omni at all. I think he called that "mental modelling"- but it has been years now.
Anyway, later we saw the author in the hallway and mentioned to him that the antenna he would be discussing would not ba an omni. The paper never was presented.

All adding a reflector underneath will do is act like lowering the antenna closer to the ground I bet .... Could you simulate something like that in EZNEC?

It would also alter the take off angle I would think

> All adding a reflector underneath will do is act like lowering the antenna closer to the ground I bet ....

The idea behind adding a reflector wire under a dipole used for NVIS, is the same as a reflector loop under a horizontal loop. They both are meant to improve the reflection (and the high angle signal), by removing most of the loss of the earth from the system.

If you live in an area with a very good (conductive) ground, it might not help much; but if you have more typical or poor ground conditions, where much of your signal penetrating the earth gets absorbed instead of reflecting, coherently, then a reflector wire or loop may indeed help.

> Could you simulate something like that in EZNEC?

Sure you can simulate it, but you may need to question how accurate it is, given the difficulty modeling earth near an antenna.

Actual observations with reflector wires under a dipole, have shown that it can make a significant improvement, but others reported no apparent difference. (I'm paraphrasing from personal experiences I've read elsewhere.)

I will not work like a quabic quad for a couple of reasons

1. Main element only 1/8 wavelength from ground causing distortion of pattern

2. Reflector is therefore much less than 1/8 from main element causing distortion of pattern

3. Reflector is considerably less than 1/8 wavelength from ground causing even more distortion of the pattern and it's probably not going to work like a reflector at all even in the slightest being more or less cancelled out by the effects of ground

You can't ignore the effects of ground on both elements, nor the fact the spacing between elements themselves and elements and ground is way off and to make a model work correctly you have to take into account the ground effects and the highly 'squashed' spacing between elements

HELLO FOR ALL;

Very good afternoon to all friends of loop antennas, see if alguine by courtesy has photos and comments about the use of TA33M Mosley, is likely to buy a second hand but in good condition, I would like to know if is good or has limitations.

thank you very much everyone, excellent forum,

Hello

I have just bought a MFJ 1788X HI-Q loop for my small backyard.
I am concerned by the flimsy mounting and lack of water proofing. I live in a windy location and in winter a very windy location with a lot of snow and ice.

The Wellbrook 1010 I also have has had to be strengthened across the top and bottom of the loop to withstand the wind and the preamp really waterproofed.

I obviously cannot put a pole across the MFJ 1788X so I am thinking wood, weatherproofing is however a very different dilemma as it stands I cannot believe water, snow and ice is not going to cause a short circuit or cause the motor that drives the variable air spaced capacitor to fail or indeed the capacitor to ice up.

Does anyone have any experience of this antenna and protection from the elements ? any advice very gratefully received.

regards to all.

The TA33M is very good beam antenna, is easy to use and repair,
and Mosley still sells parts for it.

Hi, Stephen! I have the same model, horizontally mounted on a rooftop mast with no modifications. I've had it since about 1998, and did have to replace one or two of the chokes inside the antenna housing about 6 years ago. That aside, it's a great antenna and not as flimsy as it might appear to you. If you mount it according to the manual, the apparent lack of waterproofing won't be a problem because it's designed so any water that does get into it drains right out. In fact, the manual says NOT to try to seal the housing.

The MFJ is the only small loop I've owned, and it's the best antenna I've ever had! No problem working DX on any band, including Australia and New Zealand with a 5-Watt transciever.

By the way, I wouldn't call northeast Indiana particularly windy but we do get our share of snow and ice, and the usual thunderstorms in the spring and summer.

Helo Pete, that is very encouraging. I have been wondering about horizontal v
vertical and for the moment will go vertical on a small rotator
and test it out. If all goes well might then try horizontal above the house and
without the rotator but the wind loading on the antenna does concern me.

Has anyone reverse engineered the Wellbrook Loop and setup a similar
DIY formula for building your own, perhaps of copper tubing ?

Also a schematic for an amp to match that performance quality, or a
commercially available one ?

Later I have some questions about wire loops with variable caps, which I've been studying seriously and gathering components.

I'm an SWL with a current interest in the AM band, but will likely go back to shortwave soon.
My listening location is poor but I haver access to a second story roof. Poor means a building twice the height to the West and main street with lots of visable transformers on the power poles, first floor location, about 100 feet back from the power poles. I'm in L.A.
and also have some interest in DXing the Tropic Bands.

Sure,
No magic there. Check out Steve VE7SL page at:
http://members.shaw.ca/ve7sl/index.html

I think I still may have 2 or 3 double sided preamp boards here that I made up many years back if anyone is interested along with lots of pix. The only difficult part is winding the differential input transformer.

> to work like a reflector at all even in the slightest being more or less
> cancelled out by the effects of ground

You are right that its pattern won't be exactly the same as a
free-space quagi tipped on its side.

But yagi antennas (as a general class of antennas with a radiator and
one or more passive parasitic elements) can be made with all kinds of
inter-element spacings. There are the NIST spacings, or you can
optimize for bandwidth, or you can optimize for maximum gain/length,
etc. There is no one yagi design. And there are perfectly good
compact yagis with far less than 1/8 wavelength spacing ... and they
do work. Yes, the pattern will be different than a longer yagi, and
the bandwidth may not be the same, but they too are quite acceptable
antennas.

There indeed is some interaction between the reflector loop and the
earth beneath it, just as there is between every antenna and earth,
and that is somewhat of an unknown (due in part to the variability of
soil types). It's not right to say that one cancels out the other.

The fact that people have been making "cloud burners" for decades,
some adding low reflector wires under their antennas, and many finding
that it helps, can't be discarded either. I think it is definitely
wrong to say that it "won't work like a reflector at all even in the
slightest".

Regards,
Andy

K6STI (author of AO, a very nice MiniNEC engine based modeling tool) had an article in QST or QEX some years back illustrating how even HF Yagis can be tuned for best VSWR near the ground by aiming them straight up. Obviously the reflector needs to be off the ground somewhat. The results appear very much as though the antenna is in "free space". This assumes that the antenna has a good F/B ratio.
You can model this for yourself. I have used the technique for HF Moxons with perfect results. Tune them aimed into space and put them on the tower and nothing changes.

Thank you Andy and the others who responded to my request regarding the Wellbrook Loop. I've learned some key elements from those links.

Truthfully I'm good with mechanics, BUT my confidence to scratch build an antenna amp is missing.
Are their any amps available for purchase to match the performance of the
Wellbrook one, from MFJ or another company ?
In kit form would work.

Changing the subject a bit, I have a 23-inch embroidery hoop to build a wire loop with. Is Litz wire the best to use for this or will stranded or solid work almost as well ?
I bought a 381-pf variable cap; will that cover the whole 520-1700 khz range,
or do I need to have an added switched-in additional fixed or variable cap ?

Is it OK to use a soft copper 1/2" pipe for the coupling coil of a multi-turn wire
loop ?

The key performance parameter of all of these wideband loops, in my opinion,
is the nonlinearity performance.

Does anyone have a simple way to test the nonlinearity performance of a
wideband receiving loop? The challenge arises from the fact that the
antenna really must be in the circuit in order to match the amplifier's
input impedance across many frequencies.

One thing that occurs to me is to have a measuring receiver and antenna
which would dynamically measure the field strength of shortwave AM carriers
and then use that information to measure the second and third order
intermodulation products on the test device?

From: Ray Phillips
Topic: 8151 Message: 8161

Corky,

To tune across the whole extended AM band you need a tuning capacitor with a minimum to maximum ratio of nearly 1:11.
This means that your 381pF capacitor needs to have a minimum of 34pF or less. This presumes that your loop has the perfect inductance of 246uH.
As your loop will be wound in complete turns, a perfect inductance is unlikely and so you would need a lower minimum capacitor value so you have a bit of leeway, if you want a single capacitor.

Experiment with the number of turns until the loop tunes OK at the 1700kHz end of the band with the capacitor completely open (plates unmeshed). Use complete turns for coarse adjustment and then manipulate the turn spacing for the fine adjustment. Moving turns apart will raise the frequency and vice-versa. When the upper end is lined up, close the capacitor and check the frequency. If it is not 520kHZ or less, you will need to switch in an additional capacitor when tuning the low end of the band. Bear in mind that any conductor in the near field of the loop will affect its frequency and so you need to have your pick up winding(s) in place before winding on the tuning loop itself and that any capacitor switching arrangement will introduce stray capacitance and stray inductance that will also affect loop tuning.

If I was building it, I wouldn't try to make a perfect loop. I would build one loop that catches one end of the band to at least the middle of the band and a second loop that catches the other end to the middle. So there's a bit of unwanted tuning range - not the end of the world. Use a changeover switch or banana plugs to connect them.

In a small, multi-turn loop, the "Q" or efficiency (for want of a better term) is not at the pinnacle of loop Q's. This means that you don't have to be too fussy about the pick up loop. The half inch copper pipe should work fine but is overkill and is a pain to bend to shape. Just use the same wire as the loop. Make the length of the pickup loop about one tenth to one fifth of the tuning loop length. If you have to wind more than one turn then so be it.

I once made an AM loop that was more art than technology. Stood about three feet high. The loop was shaped like the sails of a polynesian boat with the base shaped like a stylised polynesian multi-hull proa (I said it was art). It had 11 turns for the tuning loop and one for the pickup loop. I started out with a guess of 13 turns and removed them one at a time until I was happy with the inductance. None of this copper wire business either; I used fine galvanised iron wire. In the middle of the day it would take an unreadable 2KW station 150 miles away and tune so that the station audio was nearly perfect and almost completely noise free - quite acceptable listening quality. Of course its performance could have been improved but it did its job well enough and was arty-farty enough to not incur the wrath of "her indoors".

Nicely working small loops are easy-peasy - it's perfecting them that makes things hard. Make your first loop with confidence but with the knowledge that it may not be exactly what

you want and that you will learn a lot that will enable you to build a better loop next time. But, be warned, trying to improve your loop can become addictive.

All the best,
Ray vk5ugs

Chris Trask has a couple of tuned and untuned loop designs. Don't discount the active short verticals either, unless you have a specific noise source you need to null they are just as quiet as an active loop if you get them out in the open.

http://home.earthlink.net/~christrask/

Down at the bottom of the page but don't overlook the other stuff he has there, especially his work on augmented amps and mixers, and the stuff on transistor evaluations.

Chris has a newer design too he posted in the file section of the Group that looks promising but I haven't tried it myself yet (Waiting until I need other parts to justify ordering the MPS6521 transistors) He uses his patented (literally) augmentation technique on the 4 main transistors.

I had problems with stability with that design but I was driving it with a 3/4" OD copper loop. Op Amps simply don't work very well with ultra low impedance input. It may be OK with the recommended wire but I wanted a larger capture area and (slightly) lower noise of the large diameter element.

A couple of tweaks though and it's a killer dual amplifier on my IQ Pro VFO to get the level up to drive a pair of +7 DBM's. Very linear and stable in that application since the input source impedance is a much more reasonable 50 ohms rather than just a couple

Wow! A 16" Admiral TV sold for $499.99 ($200 off retail) in 1950.
Imagine what that is in today's $$.

Use a long wire antenna, connected to ground, but wrap about 10 to 12 turns of it around the receiver, close to the earthy end, so that the turns wrap around the length of the ferrite former inside.i.e. not at right angles to the ferrite core. You will get coupling to enhance the performance. Mike G4HOL

You might want to check out the Q-Stick
Plus+<http://www.dxtools.com/QStick.htm>from Radio Plus+. It will
inductively couple to the internal ferrite
antenna in the G3, so no modifications required. Just set it on (or Velcro
it to) the G3 in the right position and peak the tuning for 519kHz. On
smaller radios the large, high quality, tuned ferrite in the Q-Stick can
provide a surprising boost to MW and LW reception.

If you feel a bit more adventurous, you could try building a bigger loop
antenna. You could also inductively couple it to the radio.

Are you targeting specific Navtex stations or drift netting for whatever
happens by? If targeting, a directional antenna like the Q-Stick or a large
air-core loop can be very advantageous, nulling or reducing unwanted signals
that might interfere with your intended target.

When I was a kid my Dad was the shop foreman at a small town weekly newspaper in Aledo, IL and a hand crank start small plane took off by itself from the local airstrip and flew around for about half an hour, they had to evacuate the schools and such. Dad got the pictures of it in the air and after it crashed into a cornfield. It was a big enough deal that Life magazine bought the pictures and my Dad bought the 1st color TV in town ... We sure were popular when the Wizard of Oz came on and packed'em in for Saturday morning cartoons ... Everybody was really nice to me in school for a couple of years .....

8177. Wire and Tubular Loopstick Questions

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-01-21 23:21:51 UTC
From: skyspeed77
Topic: 8177 Message: 8177

I'm almost ready to build my three loop antennas.
A few more questions first.

I ordered the amp kit from W8DIZ.
It does not seem as sophisticated or likely as effective
as the Wellbrook design, but I'll give it a try.
Frankly, the latter has parts that I do not even understand
and not being a licensed amateur, would doubt my ability to
put a working model together.

My metal loop will be a one meter diameter 1/2 inch outside diameter copper one.
I'll use it on shortwave.

I went to Apex Electrical Surplus in Southern California and someone had bought them out of Litz wire, likely the guy selling it on Ebay.
Instead for the wire Loop on a 21" x 50" wood frame I bought 13 gauge Magnet wire, which will work I assume. I also have a large spool of 20-gauge stranded.
Any opinions on the wire are welcome.

Incidentally I'm making the large frame out of almost square two chair sides from a well built Danish-style one I found for $9 at Goodwill.

I only paid $8 for the amp kit, so am still looking for something better that might give the Wellbrook a run for its money.

Last question: Do you have to match a 50-ohm design to 72-75 ohm cable ?

Thank you for all of the friendly suggestions you all have made here.

8178. RE: [loopantennas] Wire and Tubular Loopstick Questions

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-01-22 00:58:01 UTC
From: Ray Phillips
Topic: 8177 Message: 8178

Your 1metre dia copper loop antenna will be most efficient from about 13MHz to about 23MHz and will need a tuning capacitor that ranges from (about) 26pF to 82pF. It may not tune much higher than 23MHz due to its self-resonance but would tune lower with decreasing efficiency.

I took a look at the W8DIZ wideband amp circuit - I don't think using 75 Ohm cable will be a problem. But this circuit is really for frequencies above the AM band. To use it for the AM band I would suggest increasing the size of the three 47nF capacitors to about 200nF (or 220nF or thereabouts). Note: I have not tested these changes.

Here's an idea I read about. Wind a rectangular AM loop on the back of a hinged (not sliding) wardrobe door. It gives a larger capture area (and more signal) than a tabletop loop and does not take up any useful space in the room. When using the loop, it can be steered by moving the door. When not in use, it disappears behind the closed door.

All the best,
Ray vk5ugs

Must have been sometime in 1966 because I was in 2nd grade. Color had been around for a while but still too expensive for the average Joe living in a Middle American farm town, especially considering they were high maintenance and not very reliable. I can remember a lot of trips to the Radio Shack 25 miles away to use the tube tester and buy new tubes, and a couple of House Calls from the area TV Repairman over the years. All those tubes and point to point wiring I'm still amazed they worked as well as they did.

Thank you for the steer on the loop and amp Ray.
I will heed your advice.

I read about the closet door idea somewhere recently and that is where the double chair frame will go, across the room using about
20 feet of coax to get to the radio.

Ray, any other wideband amps I should consider with or without additional preselectors or whatever ?

Good on you for your help. (Is my slang OK ?)

JR,
You did not mention the date of your popular event but we had a similar
one with 30 people in the house to watch the 1953 Coronation proceedings on our
new 9 inch screen black & white TV (later updated to 12 inch via a magnifier !!!!).
Great days hi!
72, Brian.

Stick with the current amp. There are other simple amps out there but I doubt that any simple amp would have significantly better performance. Your amp comes with a nice printed circuit board and seller support - just get it all working for now and save the hard yards for your next loop.

Build your loop first and use it without the amp. This will remove one level of complexity and make any problem correction much simpler. When you are familiar with the loop on its own, install the amp. This way you will know that any problems are with only one item and can undertake problem solving without first having to identify what item is giving the grief. (crawl, walk, run is the most successful learning method)

Once you've got some experience in building a loop and an amp, you might like to scour the net for info on balanced loops and lo-noise, balanced-loop amplifiers. I've never built one but I think that a balanced loop should have superior performance over an unbalanced loop of the same size.

Your slang is correct but if you want to pronounce it like a skippy, open your mouth about one quarter of an inch and, without moving your lips, say gudonya. The reason why Aussies don't open their mouths wide to speak is to keep the flies out - good protein but they taste terrible.

All the best,
Ray vk5ugs

Subject: [loopantennas] Re: Wire and Tubular Loopstick Questions

Thank you for the steer on the loop and amp Ray.

I will heed your advice.

I read about the closet door idea somewhere recently and that is where the double chair frame will go, across the room using about

20 feet of coax to get to the radio.

Ray, any other wideband amps I should consider with or without additional preselectors or whatever ?

Good on you for your help. (Is my slang OK ?)

>

>

> Your 1metre dia copper loop antenna will be most efficient from about 13MHz to about 23MHz and will need a tuning capacitor that ranges from (about) 26pF to 82pF. It may not tune much higher than 23MHz due to its self-resonance but would tune lower with decreasing efficiency.

>

> I took a look at the W8DIZ wideband amp circuit - I don't think using 75 Ohm cable will be a problem. But this circuit is really for frequencies above the AM band. To use it for the AM band I would suggest increasing the size of the three 47nF capacitors to about 200nF (or 220nF or thereabouts). Note: I have not tested these changes.

>

> Here's an idea I read about. Wind a rectangular AM loop on the back of a hinged (not sliding) wardrobe door. It gives a larger capture area (and more signal) than a tabletop loop and does not take up any useful space in the room. When using the loop, it can be steered by moving the door. When not in use, it disappears behind the closed door.

Subject: [loopantennas] Wire and Tubular Loopstick Questions

I'm almost ready to build my three loop antennas.
A few more questions first.

I ordered the amp kit from W8DIZ.
It does not seem as sophisticated or likely as effective
as the Wellbrook design, but I'll give it a try.
Frankly, the latter has parts that I do not even understand
and not being a licensed amateur, would doubt my ability to
put a working model together.

My metal loop will be a one meter diameter 1/2 inch outside diameter copper one.
I'll use it on shortwave.

I went to Apex Electrical Surplus in Southern California and someone had bought them out of Litz wire, likely the guy selling it on Ebay.
Instead for the wire Loop on a 21" x 50" wood frame I bought 13 gauge Magnet wire, which will work I assume. I also have a large spool of 20-gauge stranded.
Any opinions on the wire are welcome.

Incidentally I'm making the large frame out of almost square two chair sides from a well built Danish-style one I found for $9 at Goodwill.

I only paid $8 for the amp kit, so am still looking for something better that might give the Wellbrook a run for its money.

Last question: Do you have to match a 50-ohm design to 72-75 ohm cable ?

Thank you for all of the friendly suggestions you all have made here.

I use a THS4304 evaluation board from TI. Because of the bandwidth of the amplifier, I can make it have plenty of gain even up into the high shortwave bands. Non-inverting gain circuit is preferable because it won't load the loop. 40 dB or more of gain is easy.

A THS3202 evaluation board can have even more gain, because you can cascade two amplifiers together. Just remember to change the input resistor to adjust gain, NOT the feedback resistor. Personally, I don't think even the cascaded configuration is as good as the THS4304.

Here's a calculator for determining the dimensions:

http://www.hamuniverse.com/jpole.html

tape the twinlead to a pvc pole, cut and tune to desired frequency, when it's all working right, put it inside the pvc pipe (hang it from the top), seal it against weather and mount it on your roof, hang it from at tree, etc...

Thanks for the suggestion Bruce.

Steve, maybe I got the last; he said he was taking off for a few days,
so probably shipped just before that, as he acknowledged the order.
The circuit is simple enough that I imagine you could DIY without the
proprietary board.

Ray, your advice is good and I intend to follow it.
I also found a copper tube loop that appeals to me for shortwave. I'll try it with a variable cap tuner first before building the amp.
I found a 3-gang capacitor in a junk shortwave from about 1950 (Magnavox) where each section has 15 rotating plates and the radio tuned 5-18 Mhz plus MW AM. I also have a new 381 pF variable cap.

http://www.kr1st.com/swlloop.htm

So, my first three will be the above shortwave loop, a 21 x 50 inch
10-turn loop for inside of a closet door, and the embroidery hoop loop
that rotates and gimbals (see site below), the last from Litz wire and the closet door one from 13-gauge magnet wire.

Any advice on how to use the 3-gang capacitor would be welcome. Their are 3 coils connected into the variable cap. Should I utilize them somehow ?

http://kr1s.kearman.com/html/hooploop.html

Want to trade countries, Ray ?

Interesting, good music on the video :)

The idea to put a jack to make the connection between the loop and the box is interesting.

How big is the loop ?

What kind of circuit did you use for amplification ?

Did you see a real improvement between this shielded loop and a coupling loop type?

I ask for these questions because I am about to build another loop (I already have a 2 m square loop with a coupling loop, it is oriented east-west, and I cannot turn it in my room). I was wondering if the signal/noise ratio would be better on a shielded one so that it could be possible to add an amplification circuit...

Many thanks.

Sebastien.

Hello Mr. Sebastien.

Thanks for the compliments!

The music is to complement the demonstration of the antenna.

This project took approximately six months for me to develop it.

The hardest parts is interacting mechanisms available to the type of antenna you want, but now is ready and works very well.

The shielded loop allows elimiar various types of noise and noise that are created by the electrical network, such as cell phone chargers, fluorescent lamps, electric fences of the residences, etc..

The circuit I use is an adaptation of a stage of MFJ enhanced by other modifications that have developed, and the result is I have an amplifier with more than 40 db of gain, a spectacle, a show, and it all while not increasing the noise.

The loop of my antenna measures 1.50, and ranges from 3400 kHz to 18.000 kHz.

It was very practical that it is spinning 360 degrees, it helps when listening and also to get rid of the interference.

Good luck with your project.

Respectfully,

Eduardo

Eduardo, you did one beautiful job on that loop !

Is the rotation motorized ?

Which MFJ circuit did you use for modification ?

Are you willing to share the schematic ?

Thank you for sharing your work. I've seen the video twice.

Hello Corky.

Thanks for the compliments. This system is manual, no motor, but is light and turn smoothly, allowing you to have a good positioning of the Loop over the radio signal.
The amp I used for my mirror circuit is the MFJ-959, part of the circuit used with minor modifications and adjustments that ultimately will function perfectly.
I have other videos on youtube on my antennas, and also on the amplifiers.

Hugs

Respectfully,

Eduardo

Eduardo, you did one beautiful job on that loop !

Is the rotation motorized ?

Which MFJ circuit did you use for modification ?

Are you willing to share the schematic ?

Thank you for sharing your work. I've seen the video twice.

Corky

8196. Magnetic Loop Tuner

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-01-27 04:31:32 UTC
From: Irv F
Topic: 8196 Message: 8196

A very simple way to tune your loop with a minimum of
construction is to look at the tuner at the link below.It uses commonly available old broadcast radio caps
and the circuitry is exceptionally simple. The
only change I would make would be to put a small variable
across the tuning cap for fine tuning.

Bear in mind that I am a QRP man (Yaesu FT-817, but using
this tuner at 5 watts and less has not presented any
problems. Using a 6 ft diameter 1/2 inch copper tubing
loop it will tune 80m nicely.

If the link gives you problems Google G3WME and look for
his loop tuner.

Irv VE6BP

http://www.rsars.org.uk/ELIBRARY/ANTENNAS%20DOCS/HF%20LOOP%20ANTENNA%20TUNER%20-G3WME-2002%20iss%201.2.pdf

Thanks Irv.
However I tried it I couldn't get to the G3WME info.

I do like your idea to put in the smaller variable cap in parallel
to the larger cap. Is there a ratio or value that would be suitable
for the 25-90 meter range of bands ?

8198. Corky - Re: Magnetic Loop Tuner

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-01-27 22:45:26 UTC
From: Irv F
Topic: 8196 Message: 8198

Hi Corky

I'm sorry you couldn't reach the site -- I just checked the
links a few minutes ago and it is still there -- and has been
for quite a while.

The small fine tuning capacitor can have any range -- all it
does is makes it easier to home in on the tuned frequency once you
have roughly approached it using the large coarser tuning capacitor.

Give the site another try -- either way -- by clicking the link or
by going to Google and using G3WME as the search term. Once you hit the page, you will have
to scroll down as he includes a few items
on the page.

Hope this helps -- it's a great link

I wonder why he cut the tubing and then spliced it at the top? Seems like it would be better if it were all one piece.

Hi!,
By the way he ' spliced ' the top joint I feel it could be to aid the bending,
i.e. two half circles being easier than a full one with 15mm tube ????
Just a thought.

8204. PVC Small Loop Plans for 90 & 60 Meter Tropical Bands?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-01-28 19:21:13 UTC
From: Ralph
Topic: 8204 Message: 8204

Been reading many articles to prepare myself to construct a "listen-only" small loop, for the shortwave broadcast tropical bands, meaning 3.2 mc to about 5.2 mc. (If able to include 49 meter band int'l band as well, say up to ~6.3 mc, well that would be a bonus.)

Anyway, I think I can design a 1/10 wavelength small loop for 90 meters and I ought to be able to get it to tune between 3 and 6 mc using a 365 pfd variable cap.

Am thinking about 27 feet of wire on a loop form about 18" on a side, meaning will need about 13 or 14 turns.

Does anybody have a more advanced plan, ALREADY EXISTING? I esp am interested in a hand in determining the structure it will rest on, which I would like to build from PVC for light weight, strength and good looks. Will need to build in an alti-azimuth slant capability, too. (I've seen stuff for 80 meters or 160 meters, but not for 90 and 60 meters, and not on PVC.)

I am sure this had already been done many times already, so am just hoping some of your more experienced hands can help a less technical fellow like myself.

Thanks and regards,

Ralph Perry

8205. RE: [loopantennas] PVC Small Loop Plans for 90 & 60 Meter Tropical Bands?

Yahoo group: loopantennas (2008 — 2012)

From: Pollock,Raphael E
Topic: 8204 Message: 8205

One of the easiest solutions is an appropriately sized adjustable camera tripod, purchasable @ Target, etc. for $20-30. I have one for a four lbs. ferrite rod antenna for MW dxing. I built a little wooden interface to attach to the mounting plane, also easy to do. Depending on how you construct your loop you could do the same or perhaps use plastic wire tie-downs to accomplish the same...

I"ll have to go with the portability idea. Felxible copper tubing is already bent into a loop when you buy it. Even so, I don't see how taking it apart helps much. One could just wear it around their neck!

Hi Irv,
This time it came up without the error message off of the top item from putting in "G3WME Antenna" on Google:

http://www.arkansas-aresraces.org/Antennas/HFAntennas/160m-6m%20HF%20ANTENNA%20TUNER%20%20G3WME%20iss%201.2.pdf

It may be more sophisticated than I need as I'm receiving only and want to cover only the 120-25 meter bands.
I don't have the knowledge of a licensed ham, so I don't know exactly how to modify that unit, however the concept is good, it seems to me.

I was also looking at the Havana Radio simple PI circuit tuner using two variable caps balanced around a coil. I'll try to find it to post the link.

http://www.radiohc.org/Distributions/Dxers/antenna-tuner2.html

http://www.radiohc.org/Distributions/Dxers/pi-tuner1.htm

Another simple design:
http://www.hard-core-dx.com/nordicdx/antenna/lab/tuner.html

Super simple design using heavy-duty surplus components:
http://www.aa5tb.com/tuner.html

I'm probably writing these posts as much for my understanding as any one else's. The antennas come first, and will be tested without tuners at first, chief among them will be an 80 ft. longwire placed in the attic with a balun and coax feed. Height about 25 feet.

What a great idea -- a camera tripod assemply to get the tilt functionality. I love it!

--- In loopantennas@yahoogroups.com, "Pollock,Raphael E" <rpollock@...> wrote:
>
> One of the easiest solutions is an appropriately sized adjustable camera tripod, purchasable @ Target, etc. for $20-30. I have one for a four lbs. ferrite rod antenna for MW dxing. I built a little wooden interface to attach to the mounting plane, also easy to do. Depending on how you construct your loop you could do the same or perhaps use plastic wire tie-downs to accomplish the same...

Hi,

There is an interesting variation of a MW loop antenna on the

same website as the magnetic loop,

www.rsars.org.uk/ELIBRARY/docsants.htm - Cached - Similar

BFBS GURKHA RADIO 1134KHz - 1287KHz LOOP ANTENNA

Broadcasting on 1134Khz , 1251KHz, 1278KHz and 1287Khz

72, Brian, G0NSL-QRP.

Ingenious idea for a frame antenna using one of those document boxes.
Just add a 1-turn coupling loop and a socket to the box and it would be
good for even more RXs.

Hi Stephen,

I ask myself the same question when I mounted 2 ALA1530 on the same pole, I wondered if spacing was critical or not. I tried various spacings and I found no difference.

Now they are pretty close to each other (15cm / 0.50ft) on the same rotator and both of them work splendid !

Hope it helps

Dominique

Thank you Dominique.

I have now mounted both on the same rotator using materials I had at home already.
The gap is about 8 cm but initial tests show the same results as before, but time will tell. I did not use the mounts supplied
by Wellbrook as I considered these very weak and would not have given any protection in high winds.

I made a suitable mounting out of wood and if the new setup works then will probably make another
mount out of plastic and perhaps increase the spacing slightly at the same time.

Nope- not hard to understand at all. But as they are on the same rotator, is there an advantage over a single loop and a 2X splitter.

time will tell. I did not use the mounts supplied
by Wellbrook as I considered these very weak and would not have given any
protection in high winds.

I made a suitable mounting out of wood and if the new setup works then will
probably make another
mount out of plastic and perhaps increase the spacing slightly at the same time.

Regards Stephen

Subject: RE: [loopantennas] 2 x Wellbrook loops

Hi Stephen,

I ask myself the same question when I mounted 2 ALA1530 on the same pole, I wondered if spacing was critical or not. I tried various spacings and I found no difference.

Now they are pretty close to each other (15cm / 0.50ft) on the same rotator and both of them work splendid !

Hope it helps

Dominique

Hello

I am about to mount 2 Wellbrook loops on one pole, a 1010 & 1530. I understand this is possible but are there considerations I should take account of, such as spacing between them.

Regards to all

From: Dominique Kremp
Topic: 8215 Message: 8221

Hi Dale,

Sorry about my "Hard to understand ?" It was just a joke ! Hope you can take it !!!

Yes, you're entirely right, a 2 ways splitter + a single loop could do the same of course and would be less expensive !

But I must say I had the opportunity to get the very last ALA1530 version some months ago. As I wanted to compare it to the "old" one and as I only had 1 rotator, I decided to mount both of them on the same rotator. So I could test them exactly under the same conditions with the same receiver (Perseus).

They feed now 2 different receivers. Very convenient indeed !

Have a look at the attached pics. Hope they can get through !

See you

Dominique

Nope- not hard to understand at all. But as they are on the same rotator, is there an advantage over a single loop and a 2X splitter.

Dale W4OP

Each antenna is connected to a receiver. Each receiver has "his" loop !

Hard to understand ?

8223. Loop feed question: should shorten both lines of the transmission line?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-02-02 22:09:11 UTC
From: alejovarona
Topic: 8223 Message: 8223

Hi all,
Yet another apartment owner looking for a compact antenna.
I've done some reading and I've gone through most of the files in the "Files" section of the group and still one question bothers me. It is concerned with feeding the loop:
I can imagine a dipole folded into a big circumference cut by half, connecting a tuning capacitor on one of the cuts and feeding the circumference on the other cut as if it were a normal dipole...

But in most of the pictures I see that is not the case. You seem to use an "inductive feed loop" acting kind of as a transformer. In essence you are connecting both the core and the braid of a coax line with a coil between them. Which is OK with me (a million loop antenna builders cannot go wrong). But then I cannot stop wondering about the consequences to my rig.

You see I've only built dipoles and yagis and so the excited element as always some dielectric separating both end points of the transmission line. So the question is: will I damage my rig if I transmit with some tens of watts to the inductive feeding loop?

Thanks in advance

8224. Re: Loop feed question: should shorten both lines of the transmission line?

Yahoo group: loopantennas (2008 — 2012)

Many people look at that and say, "Hey, that's a short circuit!"
It's a short circuit at DC, but not at RF. With a few tens of watts, you need a big honking variable capacitor capable of several kilovolts else it will flash over. A large transmitter type variable or a vacuum variable is necessary for this part. High RF voltages will be present even at a few watts of RF power.

Here's what you do, tune up the rig into a dummy load, switch over to the antenna, tune the variable on the antenna for a dip in final current, indicating resonance. Do this at the lowest power your rig will operate at. You need some sort of SWR indicator or wattmeter to do this. You also need a "chicken stick," some sort of insulated shaft to turn the variable on the loop, because it is a high voltage point on the antenna. After you know you are tuned properly, you can increase power.

The "inductive feed loop" is typically 1/5 the size of the main loop.

Let us know what you build and how it works out.

Pappy Hiram

Some of the very early Flag designs (preceded amateur use) appeared as a round loop with a resistor in the side opposite the feed. I think I have the reference here. This evolved into the terminated Flag and Pennant "loops" we are all familiar with today. Of course, they behave as phased verticals, not traditional loops. This may or may not be what the original poster is referring to.

Could be Dale. Aperiodic would suggest a non-resonant loop and a resistor would certainly help eliminate resonance!
Or maybe it was a trick question.

This evolved into the terminated Flag and Pennant "loops" we are all familiar with today. Of course, they behave as phased verticals, not traditional loops. This may or may not be what the original poster is referring to.

Anyone have experience building an aperiodic receive loop? I am trying to understand how to choose the value of the loading resistor.
Thanks,
John McKee

An Aperiodic loop antenna is not a "small" loop, but a bit larger of a loop that is unbalanced feed and has the resistor in the middle of the loop according to the ARRL Antenna Handbook. The resistor makes this look more like two closely spaced dipoles and produces more of an omni pattern. Not a trick question... but not the electrically small loops that are typically covered here.

8232. LARGE vertical loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-02-05 19:00:32 UTC
From: Brian Burns
Topic: 8232 Message: 8232

Hello All,

Well, as Yogi Berra said "Nostalgia ain't what it used to be". In spite of that, I've been bitten by the ham radio bug again after an absence of over 50 years. A couple of ham buddies from high school looked me up on the web, and one offered to set me up with his spare equipment if I wanted to renew my license.

All of which has gotten me thinking about antennas for my tree filled location here in redwood country on California's north coast. There are two tall trees, with none in between, that are separated by perhaps 200 feet that would lend themselves to supporting a LARGE vertical loop. It could be a rectangle as much as 175 feet long by 50 or more feet tall, and 10 feet off the ground.

My question is what would be an optimum use of all this space? I'm interested in all the bands from 80 through 10 meters, and will have a Harvey Wells Z Match antenna tuner for matching things up. Is there any advantage in making it as large as possible? Any trade-offs?

Thanks a bunch,

Brian Burns-the once and future K6UCD

Large vertical loops that are 1 wavelength in circumference have a low angle take off and do well for DX only on the fundamental frequency. A 270' vert. loop would do fine on 80m but on harmonics the angle would increase which is normally the opposite of what you would want.
If the same loop were horizontal, the take off angle would be high if your height is 50' but only on the fundamental. On harmonics it would become progressively lower which is desirable. Of course it takes a minimum of 3 supports. If you can make the loop larger, like 560' or so, the take off angle will then be lower on 80m also.
If you want local net coverage on 80m, the full wave horizontal loop is hard to beat. It then becomes a great DX antenna on the higher bands.

Without resorting to modeling, I would think a 1 wavelength vertically oriented loop's takeoff angle would depend entirely on where it is fed. If it's fed at the bottom (or top) , then the takeoff angle would be almost identical to a half wave dipole whose height was the center of the loop's height. This could be a real cloud warmer if the loop is hung with the bottom close to the ground. If fed on a side then the takeoff angle would be lower and more independent of height.

Brian wow you are so lucky to have those two trees. Put your loop up feed it anywhere with ladder or window line, run it to the sofit on your house, then tie it to a Balun Designs or DX Engineering 4 to 1 balun, then run the shortest piece of coax from the balun to your tuner. It will work like a hose and probably work on 160 too.

Hello Fred,

Thanks for the encouragement, but I subscribed to the "skywave" group too
and got this caution:

For multiband use you can just use a horizontal loop or a horizontal dipole
A vertical loop is only for one or 2 bands ... so think of building a dipole
or a horizontal loop with the 2 trees and a third support
Okay you would need a third pole tree mast .. whatever
But a vertical will not work multiband
Dg9bfc
Sigi

My property is long and skinny, so a horizontal loop is not practical. Any
ideas?

Cheers,

Brian

wow you are so lucky to have those two trees. Put your loop up feed it
anywhere with ladder or window line, run it to the sofit on your house, then
tie it to a Balun Designs or DX Engineering 4 to 1 balun, then run the

Over the years, my horizontal loops, at never more than 20 feet in the air, have served me well. To make them work as multi-band antennas, feed them straight in with 300 or 450 ohm line, NEVER use coax cable as it only works at ONE impedance! A good tuner will get you on all the bands, and avoid using a balun unless you intend to cook eggs while you transmit. Treat it as a doublet and tune in the same way. My present loop is 188Ft 6ins circumference and fed with 300 ohm slotted ribbon. It works well on 80 through 10 even though it was only originally meant for 60M. A loop like this is electrically quiet as local spits and sparks are noise cancelled.
Given the space, a 283 footer or even a 566 footer will put any station on the map big time.
Regards to all, Mike G4HOL

I've used horizontal loops for years. They are cut to resonance on the fundamental frequency. SWR is not 1:1 but seldom exceeds 4:1 on any band. Coax is not a problem under these conditions. A 188' loop would be a problem on no harmonically related bands and certainly ladder line should be used.
I don't understand the balun comment. I've used coax and a 4:1 balun at the antenna. On harmonics, the balun provided a better match but on the fundamental fq. the balun had more negative effects. A 1:1 balun at the antenna when using coax would help reduce radiation from the coax's shield.

The original horizontal article by Dave W0MHS in QST 1985 is available to ARRL members on their web site. Dave recommended coax and no balun. I've tried virtually every combination of feeder and they all work. Some lengths give trouble but you can play with the length a bit and overcome tuning problems. Normally, rigs with internal tuners have no problem matching a coax fed loop on any band. 60m might be the exception.

> A vertical loop is only for one or 2 bands ...

I think this caution is the same as what Steve said. It will work on harmonics, it's just that more of your signal goes skyward where it doesn't help.

But if I understand correctly, on harmonics the loop's pattern tends to flatten out somewhat into the plane of the loop. So you might get good radiation off both ends of the loop (as well as up), which might still be beneficial even if you lose that strong broadside component on the best band where it's a full wavelength long.

I don't think Sigi means the vertical loop can't be matched on more than 1 or 2 bands. It's just that the pattern is not as ideal as you'd want.

On the other hand, he does say it "will not work multiband", which is a surprisingly strong statement, and I'm not sure I've seen that before regarding loops.

Andy

Hi Steve.At resonance the feed impedance is around 110 Ohms If you feed a loop with a quarter wave of 75 Ohm coax, you will have a matching section at the fundamental freq of suitable match to a 50 Ohm rig. My 60 metre loop loves not just its fundamental freq, but with a simple manual tuner radiates brilliantly on 80 and 40 too. If it was higher above ground it would be just great on 20,15 and 10 but those bands are not used much by me. (Yes it works on them quite well, but real Dx would be better served with a much higher antenna.) Non-resonant loops are still viable, they will radiate effectively, but I believe that the radiation patterns are a more precise shape if resonance can be fitted around a fundamental figure like 3.55 or 7.1 MHz.
The balun is really a single impedance device. It was designed to feed a folded dipole with low impedance coaxial etc. A multi band loop will present it with some very odd impedances which will produce inefficiency and loss. It will still work. An antenna that is poor, when "tuned" with an auto or manual tuner is still poor, and the tuner just spares the feelings of a 50 Ohm P.A.
Best wishes, Mike G4HOL

Subject: Re: [loopantennas] LARGE vertical loop

I've used horizontal loops for years. They are cut to resonance on the fundamental frequency. SWR is not 1:1 but seldom exceeds 4:1 on any band. Coax is not a problem under these conditions. A 188' loop would be a problem on no harmonically related bands and certainly ladder line should be used.
I don't understand the balun comment. I've used coax and a 4:1 balun at the antenna. On harmonics, the balun provided a better match but on the fundamental fq. the balun had more negative effects. A 1:1 balun at the antenna when using coax would help reduce radiation from the coax's shield.

The original horizontal article by Dave W0MHS in QST 1985 is available to ARRL members on their web site. Dave recommended coax and no balun. I've tried virtually every combination of feeder and they all work. Some lengths give trouble but you can play with the length a bit and overcome tuning problems. Normally, rigs with internal tuners have no problem matching a coax fed loop on any band. 60m might be the exception.

Subject: Re: [loopantennas] LARGE vertical loop

Over the years, my horizontal loops, at never more than 20 feet in the air, have served me well. To make them work as multi-band antennas, feed them straight in with 300 or 450 ohm line, NEVER use coax cable as it only works at ONE impedance! A good tuner will get you on all the bands, and avoid using a balun unless you intend to cook eggs while you transmit. Treat it as a doublet and tune in the same way. My present loop is 188Ft 6ins circumference and fed with 300 ohm slotted ribbon. It works well on 80 through 10 even though it was only originally meant for 60M. A loop like this is electrically quiet as local spits and sparks are noise cancelled.
Given the space, a 283 footer or even a 566 footer will put any station on the map big time.
Regards to all, Mike G4HOL

Brian remember that most tuners have a built in 4:1 balun for 300 or 450 ohm feed line. Now if you have a balanced tuner like say the old Johnson Match Box you can get away from balun use altogether.
You might want to goggle vertical loop antennas and see what comes up, I was somewhat surprised at the amount of information that was there.

Hello All,

Thanks for all the suggestions! Here is a bit of clarification.

My property is actually a 1.6 acre right triangle with a 600 foot hypotenuse. My guitar shop and ham shack are squeezed up into the narrow end where it gets down to about 40 feet wide. There aren't any conveniently located trees, or much space, for a horizontal loop, so that would have to be quite low to the ground.

The two 100 foot trees that I mentioned earlier are right on the property line that forms the height of the triangle, and are separated by perhaps 175 feet.. The whole neighborhood is full of other 100 foot plus pines and redwoods. My thought is that a rectangular (inverted triangle?) vertical loop fed at the center of the bottom would put a long leg way up at the top of the tree line, and limit the length of the feed line.

Cheers,

Brian

> My property is long and skinny, so a horizontal loop is not practical. Any
> ideas?

Is your property long and skinny in the vertical or
horizontal direction? ;-)

8247. aperiodic loop antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-02-07 14:22:01 UTC
From: John McKee
Topic: 8247 Message: 8247

I saw a reference in the ARRL handbook to a aperiodic loop and from what they show, it appears to be an unbalanced loop with a loading resistor of some unspecified value at the loop mid point. The only commercial application I could find is one from usantennaproducts.com. They acquired it from Ultra Electronics of Nova Scotia, Canada. Somewhere down in the description however they say the loops are balanced so at this point I'm not sure what I'm looking at. It makes an interesting looking low profile directional receive antenna that doesn't take up acres of space or require tall support structures. If you want to take a look, go to usantennaproducts.com, select the products tab at the top of the page and then select the hermesloop.pdf datasheet. They don't give a lot of details but it's interesting reading. - John M

Hi John,
While I have not seen your link- in a previous post I mentioned that this family of antenna appears to be the forerunner of the Flag and Pennants that we use on HF today.
My current Flag is 12 X 6' and shows an excellent F/B of between 18-21dB. One must take careful precautions to ensure common mode does not squirrel up the pattern- but this is the case for any antenna whose dimensions are small compared to a wavelength.

These antennas are not any more complicated to build than loops but show a considerably better RDF- 7.4 vs. 4.0 approx- (receive directivity factor- see W8JI or ON4UN) than small loops. Having essentially a cardioid pattern, they also don't suffer from the 180 degree ambiguity issue that loops have.
Dale W4OP

From: Darren Hennig
Topic: 8247 Message: 8250

I built a few small indoor aperiodics using planar wire loops fed into a low noise, 50 ohm input in-line RF broadband amp. All that is needed to make a "loop" aperiodic is a broadband low-noise amp that accepts an input impedance of around 25-100 ohm, 50-75 is ideal. The isolating resistor in the apex or top of the loop, opposite the feed, is a non-inductive type ideally.

Tests with my units were very broadband, and fairly low noise. They definitely showed a cardioid response in behavior until getting close to the high f limit where they were more omni in response.

The arrays shown in the ARRL do not say much - these receiving loops can be multiplexed and phased to provide a steerable response.

Hello Fred,

Thanks for the link-duly bookmarked. Here is an excellent link for general loop info in case you haven't run across it:

http://mysite.verizon.net/ka1fsb/loopants.html#shapesize

Hello Andy,

The general discussion of loop antennas at the link above makes no mention of a vertical loop's working only on one or two bands.

And here is an interesting quote from his article:

"It should be noted that horizontal loops can only transmit in the horizontal plane. And that vertical loops can be fed in such a way as to either effect horizontal polarization or vertical polarization depending on how (i.e., where) they are fed. If a vertically oriented antenna is fed at either the bottom or the top, the polarization will be horizontal; if fed on the side or bottom corner, it will be vertical. If you are going to the trouble of putting up a large vertical loop, be sure to feed it to take advantage of the low angle of radiation mentioned above!"

He is recommending feeding it at the side or corner for vertical polarization-- "to take advantage of the low angle of radiation mentioned above!"

Another aspect of the vertical loop as mentioned in an earlier post by Steve:

"Large vertical loops that are 1 wavelength in circumference have a low angle take off and do well for DX only on the fundamental frequency. A 270' vert. loop would do fine on 80m but on harmonics the angle would increase which is normally the opposite of what you would want."

So, my question is, does feeding a vertical loop at the top or bottom for horizontal polarization make for the desirable lower take off angles on the higher bands as with a horizontal loop? I'm going to all this trouble because my antenna site is ideal for a very large vertical loop, and is a lousy site for a horizontal one.

I would ask KA1FSB directly if I had an email for him. Anybody know it, or how to find it? I tried QRZ.

Cheers,

Brian

Congrats Briggs!

There are a few of us ferrite loopies out and about. Many of us have used the monster ferrites from Stormwise.com. Amidon is another possible source. If you would like to see some additional detail you can go to the ultralights group file area, look in the antennas file where I have downloaded a series of "how I made it" pictures. I have also downloaded a video on Youtube (search using the term "ferrite rod antenna") to see one in action. The Brazilian friends have also made a number of videos which can be seen on Youtube. Best of luck and please feel free to ask questions...

The ferrite rods are quite expensive and there's not much choice in the materials. You might want to check out the Yahoo! ferrite rod antenna group:

http://groups.yahoo.com/group/ferriterodantennaexperimenters/

and look through the files section. John Popelish did some nice work using ferrite toroids to make a rod antenna that is far less expensive, plus you have a wide choice of materials.

8256. A couple of broadband loop and mag loop Questions

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-02-08 21:44:32 UTC
From: rdavies6
Topic: 8256 Message: 8256

I have a couple of questions for the group. The fIrst question is around the construction of a loop for my Wellbrook ALA100M. I've been dabbling with a couple of different types of wire for the loops. I found out that thin stranded wire doesn't seem to work as well as thicker, enameled cooper wire (tired up to 16 ga so far). Is there any benefit to extrapolating the thickness of the wire and building say a 15mm diameter copper pipe loop (maybe as small as 1m -1.3 m diameter as I want the loop for indoors receiving). Any thoughts?

The second question is around a design aspect of magnetic loop antenna I plan to build over the next couple of weekends. Is there any preference or characteristics to the coupling loop that is worth bearing in mind? Should it be insulated coax, or enameled cooper, should it be think, thin...or is it predominately the shape of the loop that critical? Any guidance?

Many Thanks

Robin

Robin, the optimum loop inductance for the ALA100M is approx. 5uH-6uH. This can be achieved using a square loop with a circumference of say 5-6m of RG58c (screen only). Using thin wire with the same loop size will make the loop inductance too high, with the result that the increased reactance will act as a series impedance, limiting the loops current to the amplifier. You can still make the loop a bit larger and keep the inductance low by using RG58c screen in parallel, spaced about 2 inches apart. You also have the option of using 22mm copper pipe for a 1.5m diam loop.

Kind regards

Andrew Ikin.

Andy

That's wonderful information - many thanks for the guidance. I've got some RG58 sitting around I could use to try out a 5 or 6m loop. I've also got some 22mm copper pipe as well; I was earmarking that for some mag loop tests as my new variable air cap is now ready to pick up from Jackson Bros...but I could rethink my plan around the sequence of my experiments.

Many thanks

Very good information indeed!

Could you tell, what would be the equivalent values for the ALA100L, please? I have one and just yesterday heavy snow broke down it's 'pentagon loop' :-(So now I need to make a new and better design. I'm planning to use either insulated wire (#18 AWG) or 12mm diameter copper pipe.

So which circumference would be best for ALA100L and #18 AWG wire or 12mm copper pipe?

Thanks and 73!

12mm copper pipe?"

Dear Markus,

The ALA100 has a higher input z and lower gain compared to the ALA100M, hence it requires a larger loop. A 20m wire circumference using 18 gauge is just fine. I doubt that you would see much improvement using 12mm copper pipe. If you are interested in LF you can make the loop larger.

Kind regards

Andrew Ikin.

Off-hand, one source would be ordinary carbon composition resistors in the ~ half-watt range. Take two dozen 100 ohm resistors, wired series/parallel (a dozen in series, then in parallel with another one just like it), and you get 600 ohms and it should handle up to 12 watts.

There are places that stock non-inductive resistors; I just haven't kept track of them. I think even B&W sells them (specifically for T2FD antennas), but theirs are probably not cheap.

You do need to keep in mind that 125W into one of these antennas doesn't tell you how much power the resistor needs to handle. It depends a lot on frequency. Expect that they need to dissipate more on the lower frequencies where the antenna efficiency goes way down.

Andy

Digikey sells the 5 watt version of these for about $3 each.
http://www.millsresistor.com/pdf/pg16prn.pdf

They also sell these high surge, ceramic bulk resistive
element resistors, but they are quite a bit pricier:

Where do you live? 780 (WBBM; Chicago) is fairly easy to get here in Houston, TX most evenings even without a loop--although much stronger reception with a loop. Many easy to build plans are available on the internet.

That's what got me into it, researching good AM antennas. Zip in the house, though I had a good AM/FM tuner. First time I hooked up a simple untuned loop I was amazed.

A little bit of a detour from your question, Steve, but I was looking at the WBBM site and couldn't find any mention of old radio shows. I listen to some shows on 740kHz out of toronto, the call letters are CFZM, but they never mention them, just "zoomer radio". Two old shows Mon to Thu, 10pm to 11pm. Another one if you can get them is CHML 900kHz from Hamilton, Ont. Start times vary, after sports programming is over, usually around 10pm but runs until 2pm.

Hi:

If you are wishing to create a termination load for a Rhombic Antenna, you need to have something that will take 50% of the power you intend to transmit. So for a 100 watt radio, you need to dissipate 50 watts of energy. If you are sending data (sustained traffic) for extended periods, I would consider something a bit higher in capacity. We are using a 600 watt load for a 1 KW system.

If you are interested, I can send the URL's to a number of sites that are a bit more technical.

Kevin

Still off topic- but you can also pick up an internet radio for under $100. Programming is free. YUSA is up there- they were the first OTR station on the air 24/7- initially on C band satellite. Totally volunteer with volunteer DJ's (Ronnie Milsap is one of them). YUSA is run by a ham in Dallas and his wife.

Also on Internet radio is Crimestop and others. You don't need an internet radio of course, it just frees up your computer and makes channel changing a snap.

Hi Steve
The station you are listening to is WBBM-780 in Chicago. They broadcast When Radio Was (a really stupid title for an OTR show) from 12:05am to 1:am Tuesday morning (Monday night) through Saturday morning (Friday night). It follows the CBS news. I listen almost every night, although I often fall asleep in the middle of the program. I use a RS portable, the DX396 which I bought about 8 years ago.

8277. Built A Tunable Ferrite Loop Antenna For The KA-35 For LW

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-02-14 18:03:12 UTC
From: Adam E
Topic: 8277 Message: 8277

I was working on a new loop antenna for my KA-35. If you have a KA-35 you can take a 470 pF capacitor and solder it to a left channel connector to any tunable loop antenna connection.

I took my long wave antenna coupler apart and placed in a non working KA-35 ferrite 250 turn loop antenna element soldered a variable tuning capacitor. I used 6 to 10 turns of 22 awg wire and soldered a 470 pF capacitor inside the left channel part of the jack and the other lead to the ground shielded part of the jack.

The reception was dramatically improved and I copied beacon EMR from Emory (Augusta GA) last night on 385 kHz in the living room. Kaito needs to wake up and build something like this with a switchable preamp. Soon I will try to build one with a small RF preamp soon to connect to the 470 pF capacitor.

I will have to provide pictures soon as possible when I get the time, and a demo video. This project is for hobbyist non commercial purposes only and for experimentation. There is a schematic diagram in the photos section. Enjoy.

Chris, No, It's nothing like that. It's a very simple homebrew ferrite loop antenna for LW. I have placed the schematic diagram, and wiring diagram in the "gccengineering" photos album. Regarding the amplifier, I have not added a small amplifier circuit yet, it will need to be in a different enclosure, something a little bit bigger than the small enclosure for the ferrite rod antenna. This type is a non remote type that requires a 266 pF variable tuning capacitor, that resonates the ferrite rod coil and transfers the signal to a 10 turn coil and sent through a 470 pF capacitor into the amplifier circuit within the KA-35. It's nothing more than a loop antenna like the Terk or AN-200 from Grundig. It's a very simple home brew antenna project that I want to share with everyone here who has a KA-35 or loop antenna preamp circuit in a box. Now for remote types, I will have to build a different tuning circuit and has a preamp circuit, but that is down the road.

Yes it should, I worked too hard on the diagram, I will have to make that correction thanks. Give the project try when you can if you have a KA-35 or Degen. Don't forget the series 470 pF capacitor to solder to the left channel lug. Thanks for the correction.

Sound great. I will check it out. Still, did you check out my ferrite loop antenna? Ok, I will have to get my camera out and make a video of me tuning the loop in the living room. I will check the site out.
Thanks.

Anyone have a 160m loop up? How high off the ground? How fed?

How does it work? Any pro's, con's methods in using/building?

Anyone model a 160m loop using 450 ladder line feed?

8286. Re: [loopantennas] 160m Loop: pro's, con's, model's, build

From: Dale Parfitt
Topic: 8285 Message: 8286

Is your use for 160M only? Is this for DX or local use?
If for DX, you're as well off with a dipole as high as you can get it.
If for NVIS, I guess the full wave loop has some gain compared to a dipole when mounted low. Personally, I can't see the advantage when it requires 2X the wire and 2X the supports, unless you want to also use it on higher bands- as the VSWR excursions are not as great as would be w/ a 160M dipole.

This will be an all-band loop using 450 ladder allowing it to be an all HF band antenna. The reason for little info is few HAMs have the property or methods to install such a big antenna (I've only heard of one person using a 160/80m rhombic)....

I'm installing a square 160m loop with ~75' of 450 ladder. The loop will almost be prefect E/W-N/S square with the ladder line coming off mid-east leg. Nice thing about a loop is no counterpoise needed.

I'd like to know what the pattern will be with the loop 25-35' off the ground for the various bands?

I intend to play/install the Ugly balun to see what affect this may have.

Suggest you do some more reading/research on horizontal loops to discover the advantages.....

That's a pretty common antenna. I've had several just like it. You can see patterns for each band if you go to cebik.com.
Follow the instructions to set up a free account. Cebik, W4RNL, was a real expert on antenna modeling. Once you get there, look for an article under "Tales and Technical" about large loops. "Horizontally Oriented, Horizontally Polarized Large Wire Loop Antennas"....Basically your radiation on 160m will be NVIS just like a dipole. On higher bands the angle becomes lower and max again favors the side opposite the feedline but with many smaller lobes all around the antenna.
The only real advantage to the antenna is ease of loading. The impedance doesn't become super high on any harmonic. 450 ohm feed is ok. 300 ohm ladder line will have a slightly lower swr on most bands and will be easier to match at the rig end.
Ugly baluns will not do much on 160m but this isn't too critical.
Don't expect miracles. On 20 meters, a 33' dipole at the same height will outperform it in the broadside direction. The horiz. loop is just a good all purpose antenna that takes up a lot of room.

8289. New ferrite loop configuration

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-02-21 03:54:27 UTC
From: Tom McKee
Topic: 8289 Message: 8289

Loop Antenna News and Information ForumI'm fairly new to the group, but thought that this link which appeared in a message on the ultralightdx group might be of interest.

It describes a new ferrite loop configuration that is reported to be vastly superior to anything known in the past.

The loop description starts about 2/3 down the page after the technical discussion.

Hi Ernie,

You will have to have several turns of wire on your frame to tune the broadcast band with that capacitor. I would start with about 7 turns, and experiment from there. The two ends of this winding connect to the two terminals of the capacitor. More turns=lower frequency. To connect this to your radio, make a separate winding of one or two turns of wire on the same frame. This is the pickup winding, and it connects to your radio.

Hi Steve,

A couple of companies, including Terk, make a tunable loop antenna for AM broadcast reception for about $40.00. Radioshack carries the Terk antenna. Put it in a window on the side of your house facing the radio station. Turn it so that the "edge" of the loop is towards the station.

However, for the same amount of money or even less you can build your own loop which will outperform the Terk by a wide margin-there are many plans available-just Google "loop antenna plans"...

I love radio drama--been twisting the dial for years trying to find some. If that station you want is KBBM in Chicago they are a 50kW station and should have a long range. It might be helpful to know where you are and what sort of receiver you have.

I'll second the Terk antenna suggestion. Here's a link:
http://www.ccrane.com/antennas/am-antennas/terk-am-advantage.aspx

That link is to the C. Crane website, who also sells this product (for around $100):
http://www.ccrane.com/antennas/am-antennas/twin-coil-ferrite-am-antenna.aspx

It's possible and fairly easy to make one that will out-perform both but if you have to buy tools (soldering iron, etc) it might not be worth the cost--but searching "MW Loop Antenna", as suggested, will give you some idea of what's required. My DIY loop is similar to this, but using PVC pipe for the structure:

http://thorburn.org/gary/loop/

Making antennas is fun, too, if you like making stuff, and there's lots of information available.

I apologize, in my sleepy haste I made a misleading post--antennas are hard enough without some jerk confusing people, right?

Not only did I get a station call sign ridiculously wrong (WBBC, not KBBC in Chicago, sheesh!) but I also linked to the first antenna design that looked slightly like mine without even reading the site.

So--besides the Terk Advantage, for MW I have a simple DIY tuned loop, 36" on a side, using a capacitor--two, actually, one switchable--for tuning, not the diode used in the Thorburn site (though that does look interesting). I can't find where I got the plans but it's more-or-less like the top one on this page:

http://makearadio.com/loops/loops2.php

Sorry for the noise.

Hi Dennis (or Laura),

You might want to ask your question of a group with a wider interest,
such as this one:
http://groups.yahoo.com/group/Shortwave-SWL-Antenna/

You probably need several antennas to complement your radio so folks
will tend to ask pointed questions about what it is you want to listen
to, how much space you have, how much money you want to spend, that kind
of stuff.

Keep in mind that to some people you questions sounds something like "I
have a car, what tires should I get?" and to others like "I have some
tires, what car should I get?" I counsel humility and persistence.

Craig.
Looks like the MC1490 is long gone. I found a site that equates it to the TL701 however you might want to email the author K6QGH. His email address in on QRZ.

> I have a Globe Traveler G3,(AM/FM shortwave Radio with SSB and RDS)
> and I would like an antenna to compliment the radio.

Two antennas at minimum. You can make a loop antenna, but it will involve more construction and electronics expertise than you probably want to deal with. And it would probably only cover one band. A lot of us make them for AM.

The best thing you can do, assuming you have an external antenna terminal, or you can at least attach a wire to the radio's whip antenna (I have no idea what the radio looks like) is to attach a long wire to the radio. Run it away from electrical interference sources such as computers, TV's, those _____ CFL light bulbs, light dimmers, and automatic night lights. Make the wire as long as you can, I used to run one around the perimeter of the fence on my property. That will take care of AM and shortwave.

For FM, you need at least an FM dipole wire antenna. Preferably an outdoor FM antenna (TV antennas will NOT do). But only go to the trouble if you have two screws on the back for external FM antenna. Generally speaking, portables make very poor FM DX units, but I have seen exceptions.

You would do well the check the Ultra-Light group. Although the G3 does not qualify as an Ultra-Light, the antenna information is collateral.

A bit dated - but I thought my recent purchase and experience might be of some importance.

My experience with loops goes back to the mid 60's when I experimented with 7" non-descript ferrite rods from Lafayette Radio - and, eventually, TI TIS-34 jFETs. I have built large & small box loops - even remotely tuned. My experience with broadbanded low-Z loops is rather limited. My biggest awakening has been on parts acquisition - CATV transistors seem all but impossible to find these days. I took the simple way out - I spent money - and bought 'someone else's loop'. I considered the Wellbrook - until I heard about the modular Pixel Technolgies RF Pro-1a. Made in USA - like my last receiver - a Palstar R30A was a plus, too.

I tried it in my shack - and it could null some noise sources. I mounted it on a 5ft mast - in turn, I mounted the mast with a wall bracket to the end 2" x 8" plate on my deck, maybe 2 ft off the ground. With the loop parallel to the house - internal noise sources are effectively nulled. Only a faint hint of the aperiodic coronal discharge from a power pole is heard - <S1 in the few empty areas 10-18 MHz I tried. Atmospherics, signals, etc, overshadow the coronal discharge at lower frequencies - early afternoon - evening.

In my case, this loop is a winner - just what I needed. It covers LW quite well - I have never heard even the local 'BH' aeronautical beacon on 224 kHz so clean. Sure, it was a few bucks - you'll have most of half a kilobuck in the antenna and it's installation. Don't skimp on RG-6 - get the good stuff - quad shield - and a crimper for the waterproof connectors, too. DOn't forget a ground rod - recycling old coax (RG-8/11) makes a great ground wire - parallel the inner & outer connections. I am happy!

John

Topic: 8285 Message: 8304

Whoa! Any full size horizontal loop will have a feed point impedance of around 110 ohms. If you want to match that to your transmitter, (50 ohms), use a quarter wave of 75 to 80 ohm twin (don't forget the velocity factor) and you will have a low loss and efficient set-up. The use of twin of higher impedance than 75 ohms is to obtain a medium impedance match for multi-band working. As a large loop is used on its harmonics for the higher frequencies, the feed point impedance changes from band to band, but, generally, is in the "medium impedance" range. Your 160 metre loop on 20 metres will produce rather low angles of radiation, and be a horizon kissing loop on 10 metres.The W4RNL Cebik site will provide you with detailed information about radiation patterns, and is the wire antenna bible on line. A common misconception about horizontal wire loops is that they warm the ground beneath them. This is not the truth. The ground beneath will act as a reflector, and the degree of that reflection is all about ground conductivity (soggy soil or desert sand), and spacings between ground and antenna. The ground beneath any antenna will affect the radiation pattern, and why loops are singled out as somehow worse than other types of antennas is beyond me.
Baluns are rf transformers intended to match in ratios of 4:1 or 1:1 in the most common types. If you have a 4:1 balun attached to 110 ohms antenna impedance, then the transformation will be down to around 27 ohms, (not a good idea). Baluns are not intended for multiple impedance use. However, if you need to fry eggs in your shack, they could help. Avoid using coaxial cable, (very singular impedance stuff) and you will not need a balun. Twin feeder into a balanced antenna tuning unit is the obvious solution. Read up on doublet antennas and apply the same tuning practice to loop feeders instead to achieve great results.

Subject: [loopantennas] Re: 160m Loop: pro's, con's, model's, build

This will be an all-band loop using 450 ladder allowing it to be an all HF band antenna. The reason for little info is few HAMs have the property or methods to install such a big antenna (I've only heard of one person using a 160/80m rhombic)....

I'm installing a square 160m loop with ~75' of 450 ladder. The loop will almost be prefect E/W-N/S square with the ladder line coming off mid-east leg. Nice thing about a loop is no counterpoise needed.

I'd like to know what the pattern will be with the loop 25-35' off the ground for the various bands?

I intend to play/install the Ugly balun to see what affect this may have.

Suggest you do some more reading/research on horizontal loops to discover the advantages.....

> If for DX, you're as well off with a dipole as high as you can get it.
> If for NVIS, I guess the full wave loop has some gain compared to a dipole when mounted low. Personally, I can't see the advantage when it requires 2X the wire and 2X the supports, unless you want to also use it on higher bands- as the VSWR excursions are not as great as would be w/ a 160M dipole.

Topic: 8305 Message: 8305

I want to use a bipolar stepper motor to control tuning cap on a loop project. I would like manual control of speed and direction as well as single step use. Could anyone sugest a simple contol option?

Thanks
Ron
VA3RDR

PS
I do not want to use computer control.

Hi Ron,
A different approach might be to use one of the Chaparrel servo motors used in the C band feedhorns.
This gives you pretty much 1:1 control over the cap from a remote location- 3 wires: (+) (-) and pulse. I would think a good ball bearing cap would have low enough torque to be turned by the servo.

I had a little different approach. I had two good quality motors - very efficient ones, and I hooked them up back to back. Spin one shaft, the other motor shaft spins with a fair amount of torque - one acting as generator and the other as motor. Definitely an "analog" solution to the problem, but also one with infinite resolution. Tuning remotely was pretty easy, but I found that the motor outside got a little sluggish in temperature extremes.

I've since moved on to varactor tuning of the outdoor loop. It sure made the interface box smaller!

8309. Re: Pixel Technologies RF PRO-1A Shielded Loop vs Wellbook ALA1530

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-01 02:04:09 UTC
From: k7uxo
Topic: 7910 Message: 8309

I am a recent owner of the Pixel loop too. My impressions are mixed between excited and disappointed.

I am excited because the thing actually works, and seems to work well. Signal strength is not as good as my 180 foot wire on higher frequencies, but on lower frequencies it does well on siganl strength. The main thing is the noise is gone. All the power line "buzzzzz" is history - which makes for a nice signal to noise and clean readable signals.

What is disappointing is the build. The loop itself is parts from home depot mostly. That in its self is not a problem, because things can be replaced locally and inexpensively. It is how it is put together that is bothersome.

The shielded portion of the loop is aluminum tubing. It is attached at the bottom by pop rivets. This is an electrical connection as well as a mechanical one. The wire inside the loop is very small gauge, about 18 or 20 gauge by the look of it... maybe even as small as 22. What is clear about this design, is they did not do much to minimize resistance like you would in a transmitting loop. There is a heavy reliance on the loops ability to reject noise, and the preamplifier to boost the signal. I wonder how well this loop will work when exposed to weather for some time, and these connections become loose and weathered.

As it is, I feel compelled to rebuild parts of the loop. Increase the wire size to about 6 or 4 gauge, and a more reliable electrical connection at the bottom of the loop.

David McGinnis.

8310. log periodic loop antenna

From: chen_long614
Topic: 8310 Message: 8310

Hi all, I am newbie of antenna fabricate!
I would like to design an log periodic loop antenna. Each dipole element in log periodic array are replace by a full wavelength loop antenna. I am facing some problem in simulate and design the antenna.
I am using the CST software.
Antenna characteristic:
1.50 ohms coaxial cable is use to connect the antenna
2.Frequency range = 840-960 Mhz

Problem:
1. The impedance part. I am not idea how to deal with the impedance matching.
2. How to design a balun for it.

If anyone got idea or experince with this antenna design please share with. I am looking forward for u help.
Thank you
Thank you

8311. unshielded multi turn loop question

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-02 00:52:31 UTC
From: Sam
Topic: 8311 Message: 8311

This is to be a receive only direction finding loop, that I plan to use to chase down some local power line rfi, that is interfering with my reception from 160m through about 11mhz. Strangely it's quiet above 12mhz. I think that means it's further away from me than just within a few block area. Perhaps as far out as a mile or so.

I want to build a multi turn loop. I would like to enclose the turns inside a 32" diameter plastic hula hoop. I don't have any of the ribbon wire I have seen used for this. So I was wondering if I just kept feeding a single wire inside the 5/8 diameter hula hoops tubing, would that work OK? I'm sure the wires would end up rather scrambled as opposed to being nicely laid out next to each other like they would be if I used a ribbon wire.

Second question: I hope to be able to use this loop for about 3mhz to 11mhz. Does this seem likely with the 32" loop circumference? I would rather not build this in a larger form, as it would be harder to transport and handle while searching.

TIA,
Sam K5OAI

WHY do you think you need a multi turn loop for 3 to 11 MHz?

I built a 24" single turn shielded loop made of RG-214,
and I had to add about 11,000pf to get it to tune to around 3-4mhz
so I decided I needed to up the inductance
so I could reduce the capacitance

I just placed the capacitance across the inner loop ends
then grounded one side of the loop
http://www.k5oai.com/rfi/2011/images/ARRLHB88loop.png

and then tried feeding it with mini coax
but the nulls were not at 90 degrees to the loop axis
instead they were skewed maybe 40 degrees off the loop axis

so I tried feeding it with a 2 turn loop on a FT37-43
and attached the mini coax feed across a 10 turn secondary

still got the skewed pattern
gave up on that part of the problem for now
and decided to try an unshielded loop

P.S.
if anyone is interested in my rfi chase journal

the following was wrong:
> I just placed the capacitance across the inner loop ends
> then grounded one side of the loop
> http://www.k5oai.com/rfi/2011/images/ARRLHB88loop.png

it should have said:
grounded both ends of the shield of the loop
then attached the ground side of the coax feed to ground
also grounded one side of the capacitor
then attached the coax center to the other side of the capacitor

as shown here:
http://www.k5oai.com/rfi/2011/images/K9FD-style-loop.png

> and then tried feeding it with mini coax

I took about 10 feet of coax, put a plug on one end for my Sangean radio, taped it to a broom handle and stripped back a couple of feet at the end and formed a loop.....Center soldered to shield. Of course it had no gain but it is very directional and just fine for sniffing around the house for noise on any frequency. If you're thinking about DXing then you will need some amplification.

Topic: 8311 Message: 8318

question
were the nulls exactly 90 degrees to the loop
and were the peaks directly inline with the loop?

what throws me off is my nulls
were off on an angle like 30-50 degrees
rather than the 90 degrees they should have been
that was what is messing with my head
makes it hard to really determine where the noise source is

That's the same fellow who years ago claimed that baluns, transmission
line transformers, and transmission lines did not exist. He then went on to
reinvent the exact same things in his own words. He was thrown out of a
number of lists for that.

Did you feed the loop balanced or unbalanced? To get the nulls at 90 degrees you need to feed it balanced. An unbalanced feed will cause the null to vary with frequency.

I saw one of these at the Orlando hamfest a couple of weeks ago, but didn't think to check to see if it could be weatherproofed better. Do you think it be possible to weather-seal the bottom joints with some large heat-shrinkable tubing?

8322. Building Small Loop for 3 mHz - 6 mHz . . . Seeking Guidance and Comments!

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-03 18:17:00 UTC
From: Ralph
Topic: 8322 Message: 8322

Starting out now to build my first shortwave loop in 30 (honestly!) years.

My plans will put 3 turns of wire on a square that is 18" on a side, for a total wire length of about 18', well within the .05 - .1 wavelength guideline.

Picked up a vernier reduction-tuned 365 pfd capacitor which feels like velvet.

The part that has me excited is that I'll build the frame using all 1" PVC parts and tubing, acquired at my friendly local Home Depot.

And the swivel base (including up/down for alti-azimuthal capability) will be thanks to a cheap but good-looking tripod I picked up at Wolf's Camera.

Only open question right now is how I'll mechanically affix the loop frame to the tripod base. Still thinking about this one . . .

ANYONE WANT TO PROVIDE SOME WISDOM before I get going, in earnest? What haven't I thought about? Should I make it 4 turns, and thereby add another 6' of wire, for a total of 24 feet?

8323. Re: [loopantennas] Building Small Loop for 3 mHz - 6 mHz . . . Seeking Guidance and Comments!

Hi Ralph,

What about using a PVC T fitting in the middle of the bottom run of pipe. Then you could run a very short length of pipe down from the T to a flanged fitting. The flanged fitting could be bolted to a piece of wood or metal that either has a t nut or is tapped for the 1/4-20 threads of the tripod.

Maybe the RH PRO-1A could be easier to reverse engineer ?
According to tests it seems to be working better than Wellbrooks.
If someone who has this antenna could take some photos from inside
the antenna junction box and preamplifier etc ?
How many loop wires is there inside the aluminium tube etc.

8325. multi turn loop question

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-04 11:50:12 UTC
From: Sam Morgan
Topic: 8325 Message: 8325

Well it seems my original question got lost in the static,
so I'm going to try again. I would like to know if

I want to build a multi turn loop. The loops purpose is to be a receive only
direction finding loop.

I would like to enclose the turns inside a 32" diameter plastic hula hoop.
I don't have any of the ribbon wire I have seen used for this.
Can I just keep feeding a single wire inside hula hoops tubing,
until I fill up the 5/8 diameter tube?
The wires would end up rather scrambled,
as opposed to being nicely laid out next to each other,
like they would be if I used a ribbon wire.

Again, my ONLY QUESTION here is.....
will the scrambled method of a multi turn loop work just as well,
as the nice neat ribbon wire one wire next to only the next wire configuration?
Or must the wires all be in an neat side by side layout,
like they are in a ribbon wire?

TIA

Hi !
At least I have done a shielded loop described in here:
http://radiomagonline.com/tutorials_tips/engineers_notebook/radio_shieldedloop_am_antenna_2/
and when I compared it to my loop with tradiotional multiturn. design (variable cap. etc) there was no difference. The directivity was even better.
Signal strength needed little amplification.
Easy to build for testing.

Sam
A scramble would coil is what you are describing and it will resonate just like one that is neatly wound however distributed capacitance between the wires would be uneven. In most applications it would not matter but as to how this would affect the directional properties of a loop isn't clear. I haven't seen the matter addressed. I think using multiconductor cable would be a better way to go. At least it won't leave you wondering.
We questioned why you needed more than one turn though. If you use any of the loop antenna calculators (Google on this), you can see that one turn of wire 32" in diameter will resonate across most of the SW band when using a 365 PF capacitor. An extra turn would put you down in the AM BC band. Check out: http://www.angelfire.com/mb/amandx/loop.html

that calculates for a square loop
not a circular loop, correct?

why I thought I needed more turns was,
that using an MFJ-259B
I found the resonant point
to be higher 5-7mhz
than the 1-7mhz I was wanted in my initial design

guess I'm guilty of believing my test equipment,
on my specific loop as it was built,
rather than what ya'll were telling me,
because it didn't match with the results I am seeing,
does that make it clearer?

perhaps the fact my loop was shielded rather than unshielded
and the capacitance internally of the shield to center
thrown in the mix was causing the difference in resonant frequency...?

Yes the shield to center capacitance would make a huge difference. Figure 12 to 20 pf per foot or so.

Subject: Re: [loopantennas] multi turn loop question

that calculates for a square loop
not a circular loop, correct?

why I thought I needed more turns was,
that using an MFJ-259B
I found the resonant point
to be higher 5-7mhz
than the 1-7mhz I was wanted in my initial design

guess I'm guilty of believing my test equipment,
on my specific loop as it was built,
rather than what ya'll were telling me,
because it didn't match with the results I am seeing,
does that make it clearer?

perhaps the fact my loop was shielded rather than unshielded
and the capacitance internally of the shield to center
thrown in the mix was causing the difference in resonant frequency...?

Sam,

measure the circumference of your hoop and add 3 inches.

Cut straight lengths of your wire to this length. One wire for each turn. Uniquely label each wire at both ends.

Lay the lengths together. Tightly tape the ends into a bundle at each end. Using an electric screwdriver, hand drill or a power drill on s-l-o-w, twist the lengths together until you get about two or three turns per foot. Keeping the bundle straight with a little bit of tension makes for a neat job.

Feed the twisted wires through the hoop. Remove the bundling tape and join the wires end-to-end following the previously added labels to identify each wire. Solder and insulate the connections.
You don't need to follow any sequence of connecting so long as you don't join any wire onto itself. For convenience, you might like to join the end of wire 1 onto the beginning of wire 2, end of wire 2 onto the beginning of wire 3 etc. You will eventually get left with the beginning of wire 1 and the end of wire n; these are your capacitor connect points.

Voila - one twisted, multi-turn loop!

If you want, you can put in more than the estimated number of turns and, if there are too many turns, disconnect them one at a time until the right inductance is reached. Or wire in a fancy switching arrangement to change bands with the one loop.
You can leave the unused wires in the loop - just insulate each end and leave it hanging. If you start joining loose ends together you might create shorted turns and that ain't good for loop performance.

All the best,
Ray vk5ugs

Subject: [loopantennas] multi turn loop question

Well it seems my original question got lost in the static,

so I'm going to try again. I would like to know if

I want to build a multi turn loop. The loops purpose is to be a receive only

direction finding loop.

I would like to enclose the turns inside a 32" diameter plastic hula hoop.

I don't have any of the ribbon wire I have seen used for this.

Can I just keep feeding a single wire inside hula hoops tubing,

until I fill up the 5/8 diameter tube?

The wires would end up rather scrambled,

as opposed to being nicely laid out next to each other,

like they would be if I used a ribbon wire.

Again, my ONLY QUESTION here is.....

will the scrambled method of a multi turn loop work just as well,

as the nice neat ribbon wire one wire next to only the next wire configuration?

Or must the wires all be in an neat side by side layout,

like they are in a ribbon wire?

TIA

Interesting idea Ray. I guess one could just use some CAT5 with its 4 pairs.
Of course I suppose the twisting will add some capacitance.

If I was using that wire, I would parallel the twisted strands into a single, two strand conductor. That pair has less capacitance to the neighboring pairs than each of those wires has to the other of the pair. That gives you 4 turns per loop of cable.

Well I don't know about this wire twisting idea.
CAT5 cable has 15pf per foot. If the loop is 8 ft. in circumference and you have just 2 loops you could wind up with 240pf and limit the high frequency tuning. I'm thinking the wires need to be separated considerably more.

To put some numbers behind the idea that it matters what strands you choose for successive turns, using Cat 5 cable, I ran a few tests of capacitance per meter, paralleling two groups of 4 strands, each group (assuming you would make a 2 turn loop out of a piece of cable), using a 3 meter length of cable.

The results are:

All striped whites grouped and all solid colors grouped, 188 pF/m

Green and blue pairs grouped, brown and orange pairs grouped, 107 pF/m

Green and Brown pairs grouped, blue and orange pairs grouped, 67.3 pF/m

Green and orange pairs grouped, blue and brown pairs grouped, 67.3 pF/m

Other cable samples may swap the last three results around (because it depends on the order of colors around the bundle), but I think the contrast between the first result and the other 3 would stand pretty well.

The result matrix gets more complex when there are 4 groupings (for 4 turns around the loop), and even more complex hen all 8 strands are connected in series for an 8 turn loop. There is also the problem of what to do with the other strands while you measure the capacitance two subsets that do not make up the total. I suspect the most useful way to perform those tests would be to actually make a rigid loop (say, with a hula hoop) and measure the self resonant frequency of each of the different series combinations in effective free space.

But I am willing to predict that the highest self resonant frequency in the 8 turn case would occur if adjacent turns were made up of the two strands of each twisted pair, so that the highest turn to turn capacitance had the least signal voltage (1/8th of the total loop voltage) across that highest strand ot strand capacitance. The worst case may be connecting all the solid colors in series, then connecting all the striped whites in series, in the same order. But I am not as confident of that result.

I use a North Hills balun for measurements of balanced amplifiers, but a home brew balun should work as well.

Of course, it should be checked to verify the balun does not contribute to the IMD test floor. This can be a problem when the amplifier has an OIP2 > +100 dBm and OIP3 > +50 dBm.

For a loop amplifier having a very low input impedance and a balanced input, I have a 4:1 BalBal transformer with a balanced L-pad that is tailored to the amplifier input impedance. I use a similar arrangement for making noise figure measurements, except that the transformer is a 4:1 UnBal and I carefully determine the power loss so as to correct the NF measurement.

I ve had one of these Pixel beauties for some time and have spent some time looking under the hood. This is definitely not something that is easily reversed engineered and not something I would recommend for a DIY project. First of all the 30 dB preamp is very complex and has many transistors, tuning adjustments and exotic hard to get parts in it that are not readily available off the shelf. It has a very low noise figure and world□class intermod specs (OIP3 near 50 dBm and OIP3 over 110 dBm) that are much better than any receiver I've ever seen. There is nothing like this commercially available at a reasonable price. The one I have also has some very expensive Litz wire inside the tubing that is also hard to get. I would recommend that you search the posts by Chris Trask on this board. He has some schematics posted and some plans for a Moebius loop. While you won't get the "Ferrari" performance of the Pixel loop a "Ford" may get you to the same place.

Initially I saw the Pixel antenna demonstrated at a local Ham show and was quite impressed with it. They had it setup indoors under some arc lights that were in the convention hall that also had a metal roof. This was probably the worst place possible to demonstrate an antenna. They did an A/B comparison against an active dipole antenna that MFJ sells. The results were simply amazing. The loop was able to achieve crystal clear reception while the active dipole was swamped with noise from the nearby arc lamps across most bands.

I purchased one and when I got it setup I was not disappointed. It was much more quite than any antenna I have ever tried. (and I have tried many in my restricted location including a k9ay loop). The local noise from my neighbor's plasma TV and the local power line crude were greatly reduced or completely gone. I'm hearing stations I've never heard before. I'm a very happy camper and for $400 I consider it a great value.

Relative to the build quality and weather resistance, I was actually quite impressed (unlike some others.) I pulled off some of the covers on the preamp and loop and it looks like all of the circuit boards and electrical connections are conformal coated and all of the mechanical joints and fittings were hermetically sealed with silicone or rubber gaskets.

The outdoor preamp is in a nice die cast aluminum enclosure and is painted white to reduce solar heating in hot climates. (A nice touch for my location.) Also all of the required hardware, jumpers, adapters and cables for mounting and installation were included. They use rivets to attach and secure the aluminum tubes, but to me they seem very sturdy, electrically sound and mechanically robust.

Poor means a building twice the height to the West and main street with lots
of visable transformers on the power poles, first floor location, about 100
feet back from the power poles. I'm in L.A.

From: AlienRelics
Topic: 8345 Message: 8345

Sorry about the spam that slipped through.

FYI, I'd prefer that if you see spam on the list, in the files, links, calendar, database, etc. that you NOT post on the list about it. Instead please email the listowner address directly
loopantenna-owner@yahoogroups.com and let me know about it.

That way I can take care of it with the minimum of fuss.

Thanks,
Steve Greenfield AE7HD
Your friendly neighborhood moderator

I was NOT talking about lexluthor. His post is on topic. Sorry for any confusion.

I was talking about a message that was clearly spam, completely off-topic. I've already deleted it and banned the poster.

Stephan:
i have no affiliation with Pixel. Just a very happy customer. It solved some problems that I haven't been able to solve with any other antenna. You might want to look at the reviews of this antenna on e-ham.net. Lots of others have found this antenna a great performer as well.

8348. Use antenna analyzer?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-12 23:56:03 UTC
From: Brian Burns
Topic: 8348 Message: 8348

Hello All,

An antenna analyzer looks like a useful tool, but I wonder if one gets used much after getting an antenna tuned up. I would buy one to use on the big vertical loop that I'm planning, but I figure that it would just sit on the shelf and gather cob-webs after an initial use. Anyone got one to rent?

Cheers,

Brian Burns

Hello

Bit of a long shot, but does anybody have any knowledge or experience of the WiMo baby loop.
I am using an MFJ-1786 which is surprisingly good and now want a second TX loop.

Unfortunately I cannot find any meaningful feedback on the WiMo which is puzzlingly me, maybe nobody is buying them.

Regards to all

Stephen

It seems to me that the reason there aren't more review
on the WIMO baby loop is that it's almost $1500.
Try these links below.

Hello Mike,

“Well this is what radio clubs should be all about. Sadly, many appear to fall short. Mike G4HOL”

Despair thee not my friend. All we have to do is to keep following Steve Ratzlaff’s example of generosity, because what goes around does truly come around. I just this morning took delivery of a complete ham station on permanent loan from Dennis Regan K6ZJU. I helped him get started in ham radio 55 years ago when we were both still in high school!

Dennis and another high school buddy, Wayne Mills N7NG looked me up through the internet, and Dennis offered to outfit me completely with spare equipment if I wanted to get back into ham radio. No Heath AT 1’s and ARC 5’s either—a Kenwood TS-530S, a couple of antenna tuners, G5RV antenna etc., right down to the J-47 straight key! I’m just now opening up the boxes.

Cheers,

Brian Burns….. once and future K6UCD

Brian,

Totally off the subject, but Wayne and I were neighbors and I helped him get started in ham radio way back then. He was just at my house with his wife on January 28th and 28th. I don't recall knowing you, but I was W6TUZ and graduated from Sequoia in '55. I decided to get back in ham radio a couple of years ago and now I am KI6RXY.

Well it is a small world isn’t it! Wayne stopped by my place on that trip up to Fort Bragg which must have been about the same time. His wife grew up in Fort Bragg and they were married here about a thousand years ago! They were up here to visit relatives.

I started at Sequoia in the fall of ’55 as a junior, having moved from southern Texas where I was W5BRO. I must have just missed you. I’m the guy that got given the diathermy machine by my foot doctor. I traded the huge power transformer to Wayne for something or other, and he still has it—using it for a door stop I suppose.

Where are you located now?

Cheers,

Brian

Wow. Now I remember Wayne talking about visiting a "Brian" on his way up to FB. He was talking about the big transformer he got from you.

I live in Saratoga; where do you live? Are you on the air these days and, if so, what bands do you operate on?

I hope to be visiting Wayne in June as we finish a cross country road trip.

Hello David,

Wow. Now I remember Wayne talking about visiting a "Brian" on his way up to FB.
He was talking about the big transformer he got from you.

I'm in Fort Bragg where we moved 10 years ago after 31 years in Palo Alto. Wayne came by on a Sunday afternoon. We spent a couple of delightful hours talking about old times at Sequoia, and what we had done with our lives, and he gave me some advice about hanging up the big vertical loop that I'm planning.

The big transformer came from a diathermy machine that my podiatrist wasn't using any more. It had what looked like a pair of 813's in an oscillator circuit at around 30 mhz. It had minimal rf shielding and must have put out at least 500 watts. A real monster. I cannibalized it, and traded off parts to the guys that could afford to build high power rigs.

Are you on the air these days and, if so, what bands do you operate on?

I let my license lapse in about 1960, and have to bone up on the latest regulations and technology. I got my general class ticket in Texas when I was 13, and had the call W5BRO. When I moved to Redwood City in '55 I got K6UCD, which Dennis Regan (K6ZJU) tells me is still available, so I will apply to get it again.

I used to work 40 meter cw, though Dennis and I had a delightful time on 15 meter 'phone. We built the $3.96 beam from CQ magazine (aluminum foil wrapped bamboo fishing poles), and borrowed a cathode modulator from somebody to plug into the keying jack of his cw transmitter. We worked stations on the east coast with that pitiful rig, and had a ball.

Cheers,

Brian

You can fine them at the producer site:

http://www.ciromazzoni.com/English/Loop%20Antenna.htm

They are quite popular in Italy among antenna-restricted hams.

I got a new license two years ago and have spent the entire time setting up a station so that my operation time has been minimal. I am able to get on 40 thru 10 meters. Most of my contacts have been on 20 with only a few on 17 and 15. If we were communicate on the air, I think that 40 would be the best choice. I have a vertical for 40 with a very poor ground system.

What capability do you have on 40? Also, what are the characteristics of the loop you are installing? I plan to put up a 500' loop sometime this year.

When I moved to Redwood City in ’55 I got K6UCD, which Dennis Regan (K6ZJU) tells me is still available, so I will apply to get it again.

I used to work 40 meter cw, though Dennis and I had a delightful time on 15 meter ‘phone. We built the $3.96 beam from CQ magazine (aluminum foil wrapped bamboo fishing poles), and borrowed a cathode modulator from somebody to plug into the keying jack of his cw transmitter. We worked stations on the east coast with that pitiful rig, and had a ball.

Cheers,

Brian

Topic: 8348 Message: 8360

Hello David,

What capability do you have on 40? Also, what are the characteristics of the loop you are installing? I plan to put up a 500' loop sometime this year.

Dennis has loaned me a Kenwood TS-530S which does everything on every band with over 100 watts output. I've never operated such a sophisticated piece of equipment—never seen so many knobs! But it will be a while before I get my license renewed.

I've decided to start with a small horizontal loop (180 feet) around the perimeter of my shop. It'll be quick, cheap, and mostly for receiving. I'll see if I can get out with it when I get my new ticket.

The large loop that I'm planning will be around 500 ft also, with a matching stub to get it to resonate on 160. It will have to be vertical, as that is all I have room for at my end of our triangular lot. I'm a bit concerned about the radiation angles being progressively higher on the higher bands, but I'll just see how it works on them.

Cheers,

Brian

Subject: RE: [loopantennas] Use antenna analyzer?

Hello David,

Wow. Now I remember Wayne talking about visiting a "Brian" on his way up to FB. He was talking about the big transformer he got from you.

I'm in Fort Bragg where we moved 10 years ago after 31 years in Palo Alto. Wayne came by on a Sunday afternoon. We spent a couple of delightful hours talking about old times at Sequoia, and what we had done with our lives, and he gave me some advice about hanging up the big vertical loop that I'm planning.

The big transformer came from a diathermy machine that my podiatrist wasn't using any more. It had what looked like a pair of 813's in an oscillator circuit at around 30 mhz. It had minimal rf shielding and must have put out at least 500 watts. A real monster. I cannibalized it, and traded off parts to the guys that could afford to build high power rigs.

Are you on the air these days and, if so, what bands do you operate on?

I let my license lapse in about 1960, and have to bone up on the latest regulations and technology. I got my general class ticket in Texas when I was

13, and had the call W5BRO. When I moved to Redwood City in ’55 I got K6UCD, which Dennis Regan (K6ZJU) tells me is still available, so I will apply to get it again.

I used to work 40 meter cw, though Dennis and I had a delightful time on 15 meter ‘phone. We built the $3.96 beam from CQ magazine (aluminum foil wrapped bamboo fishing poles), and borrowed a cathode modulator from somebody to plug into the keying jack of his cw transmitter. We worked stations on the east coast with that pitiful rig, and had a ball.

Cheers,

Brian

8361. Coupling Loop Question

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-15 21:05:43 UTC
From: Ralph
Topic: 8361 Message: 8361

This is a real neophyte question -- apologies in advance -- but please confirm how I should connect my coupling loop, which I am using to take the signal off my small (90 meter / 60 meter) shortwave loop antenna.

Do I

(a) solder one end of the coupling loop to the coax inner conductor, and the other end to the ground shielding? or

(b) only solder one end of the loop to the inner coax conductor and leave the other end of the coupling loop unconnected to anything; or

(c) solder both ends of the coupling loop to the inner conductor of the coax.

I want to connect this to coax because I have PL-239 jacks on my antenna tuning unit, so want to use a PL-239 plug on the coax from the small loop.

THANK IN ADVANCE!

Hi,

The coupling loop does not connect to the main loop. It is a separate loop that couples the RF to your feed line. It should be about 1/5th the size of the main loop
or 1 turn. You may have to experiment with the placement in the main loop for best signal.

This assumes that your "main loop" is connected to a fixed or variable capacitor that resonates it at some frequency of interest. Your coupling loop then acts as a one turn transformer winding to pick up the signal. One end of the coupling loop can be connected to the shield of your lead in coax, and the other end connects to the center conductor of your lead in coax.

THANKS GREGG, THAT WAS THE ANSWER I WAS LOOKING FOR! (I thought that was probably the way forward, but wasn't certain.)

The various plans I've been looking at typically don't specify how to attach a plug to the coupling loop, to feed the receiver input . . .

To others, thank you also for taking the time to reply. I didn't word my question very well. Yes, I did already understand that the coupling loop was only inductively linked (not physically connected) to the main resonant/tuned loop.

My main loop is 4 turns, and I am planning a 2 turn coupling loop.

Cheers,

Ralph

Ralph,
What is the diameter of the main loop? Unless you're looking to use it for specific need or just experimentation, not to decourage you, but you probably won't get much better results than off the whip.
But then, I'm not sure without more info. An amplified loop might be considered? The Degen DE 31 comes to mind. I'm in the process of building a small 8" 20 turn tunable SW loop with taps so as to tune a very broad range. I will be using with my Palomar base amp.

Ralph, Oops, sorry, I just noticed noticed the details I missed. (ATU, PL-239) Looks like you got what you needed, so, please disregard my suggestions. Good luck with your mag loop...
